INITIAL-BOUNDARY VALUE PROBLEMS FOR SECOND ORDER SYSTEMS
OF PARTIAL DIFFERENTIAL EQUATIONS

HEINZ-OTTO KREISS
OMAR E. ORTIZ AND N. ANDERS PETERSSON

Abstract. We develop a well-posedness theory for second order systems in bounded domains where boundary phenomena like glancing and surface waves play an important role. Attempts have previously been made to write a second order system consisting of \( n \) equations as a larger first order system. Unfortunately, the resulting first order system consists, in general, of more than \( 2n \) equations which leads to many complications, such as side conditions which must be satisfied by the solution of the larger first order system. Here we will use the theory of pseudo-differential operators combined with mode analysis. There are many desirable properties of this approach: 1) The reduction to first order systems of pseudo-differential equations poses no difficulty and always gives a system of \( 2n \) equations. 2) We can localize the problem, i.e., it is only necessary to study the Cauchy problem and halfplane problems with constant coefficients. 3) The class of problems we can treat is much larger than previous approaches based on ‘integration by parts’. 4) The relation between boundary conditions and boundary phenomena becomes transparent.

Numerical experiment are presented that illustrate various boundary phenomena.

INTRODUCTION

The theory for first order hyperbolic systems, which was developed with fluid problems in mind, is by now rather well understood. It turned out that energy estimates via ‘integration by parts’ and characteristics are the most important ingredients in the theory.

Second order hyperbolic systems often describe problems where wave propagation is dominant. In bounded domains this leads to a large number of boundary phenomena like glancing waves and surface waves. Attempts have previously been made to write a second order system consisting of \( n \) equations as a larger first order system.

Keywords and phrases: Well-posed 2nd-order hyperbolic equations, surface waves, glancing waves, elastic wave equation, Maxwell equations.

However, boundary phenomena such as glancing and surface waves correspond to generalized eigenvalues which are not handled by the theory for first order systems. Furthermore, the resulting first order system often consists of more than $2n$ equations which leads to many complications. In particular, the first order system must in general be augmented by side conditions to guarantee that solutions of the first order system satisfy the original second order system.

In this paper we describe a theory for second order hyperbolic systems based on Laplace and Fourier transform, with particular emphasis on boundary processes corresponding to generalized eigenvalues. Our theory uses pseudo-differential operators combined with mode analysis, and builds upon the theory for first order systems developed in [1, 2]. This approach has many desirable properties: 1) Once a second order system has been Laplace and Fourier transformed it can always be written as a system of $2n$ first order pseudo-differential equations. Therefore, the theory of [1, 2] also applies here. 2) We can localize the problem, i.e., it is only necessary to study the Cauchy problem and halfplane problems with constant coefficients. 3) The class of problems we can treat is much larger than previous approaches based on 'integration by parts'. 4) The relation between boundary conditions and boundary phenomena becomes transparent.

The remainder of the paper is organized as follows. In section 1 we state the general problem and provide some basic definitions. In section 2 we treat in detail the fundamental problem of a single wave equation in a half-plane subject to different types of boundary conditions. In section 3 we present a model problem consisting of two wave equations coupled through the boundary conditions and perform numerical tests corresponding to this model problem. In section 4 we treat the general problem of $n$ second order wave equations and show that it can be reduced essentially to wave equations coupled through the boundary conditions.

1. Initial-Boundary Value Problems for second order hyperbolic systems

1.1. Well posed problems

In this paper we want to consider second order systems which are of the form

$$u_{tt} = P_0(D)u + F(x,t), \quad t \geq 0, \quad x \in \Omega, \quad F \in C^\infty_0(\Omega),$$

in the halfspace $\Omega = \{x_1 \geq 0, -\infty < x_j < \infty, j = 2, \ldots, r\}$. Here

$$P_0(D) = A_1D_1^2 + \sum_{j=2}^r B_jD_j^2,$$

where

$$A_1 = A_1^* > 0, \quad B_j = B_j^* > 0,$$

are $n \times n$ constant matrices, $u$ is a vector valued function with $n$ components and we are using the notation

$$x = (x_1, \ldots, x_r), \quad D = (D_1, \ldots, D_r), \quad D_j = \partial/\partial x_j,$$

$$u_t = \partial u/\partial t = D_1u, \quad u_{x_j} = D_ju.$$

At $t = 0$ we give initial conditions by

$$u(x,0) = f_1(x), \quad u_t(x,0) = f_2(x).$$

We are interested in smooth solutions which belong to $L^2(\Omega)$ and satisfy, at the boundary $\Gamma = \{x_1 = 0, -\infty < x_j < \infty, j = 2, \ldots, r\}$ $n$ linearly independent boundary conditions.

$$Lu =: C_0u_t + \sum_{j=1}^r C_ju_{x_j} = g, \quad g \in C^\infty_0(\Gamma).$$
Here $C_0, C_j$ are constant $n \times n$ matrices, $C_1$ is non-singular and, without loss of generality, we assume it to be normalised.

**Assumption 1.1.** $C_1 = I$.

To facilitate the use of Laplace transformation in time, we frequently assume that the initial data is homogeneous, i.e., $f_1 = f_2 = 0$. This is however no restriction, since it is always possible to change variables in a problem with general initial data such that the initial data becomes homogeneous in the new variable. Since the Cauchy problem is well posed (see section 4.1) we can extend the definition of the forcing and the initial data smoothly to the whole of $\mathbb{R}^n(x)$ and determine its solution. Then we subtract this solution from the halfplane problem and obtain a new halfplane problem where only the boundary data do not vanish. This is a very natural procedure because all the difficulties and many physical phenomena arise at the boundary.

We now introduce some key definitions that classify the problems according to estimates one can achieve.

**Definition 1.2.** Consider (1)–(3) with $F = 0, f_1 = f_2 = 0$. The problem is called **Boundary Stable** if there are constants $\eta_0 > 0$, and $K > 0$ which are independent of $g$, such that for all $\eta \geq \eta_0 \geq 0$, $T \geq 0$

$$\int_0^T e^{-2\eta t} \left( \|u(\cdot, t)\|_{H^2(\Gamma)}^2 + \|u_t(\cdot, t)\|_{H^2(\Gamma)}^2 \right) \, dt \leq K \int_0^T e^{-2\eta t} \|g(\cdot, t)\|_{H^2(\Gamma)}^2 \, dt. \tag{4}$$

**Definition 1.3.** The problem (1)–(3) is called **Weakly Boundary Stable** if there are constants $\eta_0 > 0$, $K > 0$ and $\alpha > 0$, which are independent of $g$, such that for all $\eta \geq \eta_0$, $T \geq 0$,

$$\int_0^T e^{-2\eta t} \|u(\cdot, t)\|_{H^2(\Gamma)}^2 \, dt \leq \frac{K}{\eta^\alpha} \int_0^T e^{-2\eta t} \|g(\cdot, t)\|_{H^2(\Gamma)}^2 \, dt. \tag{5}$$

Here $\|u\|_{H^p}^2$ denotes the norm composed of the $L^2$-norm of $u$ and all its derivatives up to order $p$. Thus (4) tells us that we “gain” one derivative while (5) says that $u$ is as smooth as the data. The constants $\alpha, \eta_0$ are very important. If $\eta_0 = 0$, then we can choose $\eta = \frac{1}{T}$ for every fixed $T > 0$. This shows that the solution grows at most like $T^\alpha$ with time. If $\eta_0 > 0$, then there is bounded exponential growth. This can happen when lower order terms are present.

The boundary estimates allow us also to obtain interior estimates. In section 2.2 we will prove

**Theorem 1.4.** Consider (1)–(3) with $F = 0$. If the problem is Weakly Boundary Stable, then we obtain interior estimates of the form (4), (5) where $\|u(\cdot, t)\|_{H^2(\Gamma)}$ is replaced by $\|u(\cdot, t)\|_{H^2(\Omega)}$ and $\alpha$ by $\alpha + 1$, respectively.

Since we can always reduce the data such that only $g \neq 0$, we could restrict ourselves to this case. However, we are interested in differential equations with variable coefficients in general domains. Thus we have also to discuss the case that $F \neq 0$. In particular, we have to show that the problem is stable against perturbations by lower order (first order) terms of the differential equations.

**Definition 1.5.** The problem (1)–(3) with $f_1 = f_2 = 0$ is called **Strongly Well Posed in the Generalized Sense** if there exists $\eta_0 > 0$, $T > 0$, $K > 0$ and $\alpha > 0$, which are independent of $g$ and $F$ such that, for all $\eta \geq \eta_0$,

$$\eta \int_0^T e^{-2\eta t} \left( \|u(\cdot, t)\|_{H^2(\Gamma)}^2 + \|u_t(\cdot, t)\|_{H^2(\Gamma)}^2 \right) \, dt + \eta^2 \int_0^T e^{-2\eta t} \left( \|u(\cdot, t)\|_{H^1(\Omega)}^2 + \|u_t(\cdot, t)\|_{H^1(\Omega)}^2 \right) \, dt$$

$$\leq K \left[ \eta \int_0^T e^{-2\eta t} \|g(\cdot, t)\|_{H^2(\Gamma)}^2 \, dt + \int_0^T e^{-2\eta t} \|F(\cdot, t)\|_{H^2(\Omega)}^2 \, dt \right]. \tag{6}$$

Clearly, if (6) holds, then the problem is **Boundary Stable**. For first order systems the classical theory (see [1, 2]) tells us that also the converse is true: If the problem is **Boundary Stable**, then it is **Strongly Well Posed in the Generalized Sense**. As we will see, after Laplace and Fourier transformation we can write our problem again as a first order system which satisfies all the conditions of the classical theory and therefore the
results of that theory are also valid for second order systems. In particular, the problem is stable against lower order perturbations both for the differential equations and the boundary conditions. (See section 4 and the Appendix of [4]).

Due to physical phenomena like glancing and surface waves, the problems for second order systems are often only Weakly Boundary Stable. This leads to

**Definition 1.6.** We call the problem (1)–(3) Weakly Well Posed in the Generalized Sense if it is Weakly Boundary Stable and if, for $g = 0$, there exists $\eta_0 \geq 0$, $K > 0$ and $\alpha > 0$ which are independent of $F$ such that, for all $\eta \geq \eta_0$,

$$
\int_0^T e^{-2\eta t} \left( \|u(\cdot, t)\|_{H^1(\Omega)}^2 + \|u(\cdot, t)\|_{H^2(\Omega)}^2 + \|u(\cdot, t)\|_{H^2(\Gamma)}^2 \right) \, dt \leq \frac{K}{\eta^\alpha} \int_0^T e^{-2\eta t} \|F(\cdot, t)\|_{H^0(\Omega)}^2 \, dt.
$$

If (7) holds, then we can obtain an estimate even when $g \neq 0$. We split the problem into two; one with $g = 0$ and $F \neq 0$ and the other with $g \neq 0$ and $F = 0$. For the first problem we obtain (7) and for the other we use Theorem 1.4. One might be tempted to replace the requirement (7) by the weaker estimate

$$
\int_0^T e^{-2\eta t} \left( \|u(\cdot, t)\|_{H^1(\Omega)}^2 + \|u(\cdot, t)\|_{H^2(\Omega)}^2 \right) \, dt \leq \frac{K}{\eta^\alpha} \int_0^T e^{-2\eta t} \|F(\cdot, t)\|_{H^0(\Omega)}^2 \, dt.
$$

However, the definition is not stable against lower order perturbations. In section 2.3 we will give an example which is algebraically unstable, i.e., with time the solution loses more and more derivatives.

**Definition 1.7.** We call the problem (1)–(3) Weakly Unstable if the estimate (7) does not hold.

For first order systems the generalization to variable coefficients (and then to quasilinear equations) uses the theory of pseudo-differential operators and requires the construction of a symmetrizer, as described in [1], which is smooth in all variables. If the problem is Boundary Stable, then, as we have mentioned above, the same construction can be used for second order systems. If the problem is only Weakly Boundary Stable, then we have to modify the construction. This can be done but is technically somewhat complicated and the details are beyond the scope of this paper. However, we will make the result plausible.

Since the stability against lower order perturbations is crucial for the generalization of our results to systems with variable coefficients in general domains, we shall give a proof in section 1.2.

It is also well known that stability against lower order perturbations allows us to use “localization” to decompose an initial boundary value problem on a general compact domain into a finite number of problems which are either initial values problems in the whole space, or initial boundary value problems in the half space. We illustrate the technique with a simple example in one dimension.

Consider the initial boundary value problem for the wave equation on the strip

$$
u_{tt} = u_{xx}, \quad x \in [0, 1], \quad t \in [0, \infty)
$$

with initial and boundary conditions

$$
u(x, 0) = f_1(x), \quad u_t(x, 0) = f_2(x), \quad B_0 u(0, t) = g_0(t), \quad B_1 u(1, t) = g_1(t),
$$

where $B_0$ and $B_1$ are linear first order differential operators.

A partition of unity of $[0, 1]$ can be chosen as a set of three $C^\infty$ functions $\varphi_1(x), \varphi_2(x), \varphi_3(x)$ where $\varphi_1$ is a cutoff function

$$
\varphi_1(x) = 1 \quad \text{if} \ x \leq 1/4, \quad \varphi_1(x) = 0 \quad \text{if} \ x \geq 1/2.
$$

Similarly,

$$
\varphi_3(x) = 0 \quad \text{if} \ x \leq 1/2, \quad \varphi_3(x) = 1 \quad \text{if} \ x \geq 3/4,
$$

$$
\varphi_2(x) = \varphi_1(x) - \varphi_3(x).
$$
We now define the functions
\[ \eta \]
by choosing
\[ u \] and \[ \eta \] such that
\[ u(x,t) = \varphi_1(x)u(x,t), \quad i = 1, 2, 3. \]
Clearly \( u(x,t) = u_1(x,t) + u_2(x,t) + u_3(x,t) \) for all \( x \in [0,1] \) and
\[ u_{itt} = \varphi_iu_{tt} = \varphi_iu_{xx} = u_{ixx} + L_i, \]
where
\[ L_i = -2\varphi_{ix}(u_{1x} + u_{2x} + u_{3x}) - \varphi_{xx}(u_1 + u_2 + u_3), \]
consist only of lower order terms and has the same support as \( u_i \).
Defining also \( f_{1i}(x) = \varphi_i(x)f_1(x) \) and \( f_{2i} = \varphi_i(x)f_2(x) \), we obtain that \( u_1 \) solves the half line problem
\[ u_{1tt} = u_{1xx} + L_1, \quad x \in [0,\infty), \quad t \geq 0, \]
\[ u_1(x,0) = f_{11}(x), \quad u_{1t}(x,0) = f_{21}(x), \quad B_0u_1(0,t) = g_0(t). \]
\( u_2 \) solves the initial value problem on the whole line
\[ u_{2tt} = u_{2xx} + L_2, \quad u_2(x,0) = f_{12}(x), \quad u_{2t}(x,0) = f_{22}(x), \quad x \in (-\infty,\infty), \quad t \geq 0. \]
and \( u_3 \) solves the half line problem
\[ u_{3tt} = u_{3xx} + L_3, \quad x \in (-\infty,1], \quad t \geq 0, \]
\[ u_3(x,0) = f_{13}(x), \quad u_{3t}(x,0) = f_{23}(x), \quad B_1u_3(1,t) = g_1(t). \]
If the three problems for \( u_1, u_2 \) and \( u_3 \) are well posed, then the original problem (9)–(10) is well posed.
To treat variable coefficient problems one can invoke what is known as the “principle of frozen coefficients” to replace the problem by one with constant coefficients. Heuristically, one can think that if one localizes the problem to very small regions then the coefficients of the equation in each region are nearly constant and the behavior of the solution is near to that of an equation with constant (frozen) coefficients. The proof of the validity of this requires the use of pseudo-differential theory. Here we claim the validity of this principle for our problem but do not go into the details.

1.2. Stability against lower order perturbations

If the problem is Boundary Stable, then it is strongly well posed in the generalized sense and therefore stable against lower order perturbations. We shall now prove that the corresponding results hold for weakly well posed problems.

**Theorem 1.8.** Consider the problem (1)–(3) for \( F = 0, \ g \neq 0 \) and change the boundary conditions (3) to
\[ Lu = g + lu, \quad |l| \text{ bounded.} \] (11)
If the problem is Weakly Boundary Stable, then the same is true for the perturbed problem.

**Proof.** We consider \( lu \) as part of the data. Then (5) becomes
\[ \int_0^T e^{-2\eta t}||u(\cdot,t)||^2_{H^0(\Gamma)}dt \leq \frac{2}{\eta^2} \left( ||l||^2 \int_0^T e^{-2\eta t}||u(\cdot,t)||^2_{H^0(\Gamma)}dt + \int_0^T e^{-2\eta t}||g(\cdot,t)||^2_{H^0(\Gamma)}dt \right). \] (12)
By choosing \( \eta_0 \) such that \( \frac{K}{\eta_0^2}||l||^2 \leq \frac{1}{4} \), we obtain an estimate also for the perturbed problem. \( \square \)
Theorem 1.9. Consider the problem (1)–(3) with \( g = 0 \) and change the differential equations to
\[
    u_{tt} = P_0(D)u + P_1(D)u + F.
\]
(13)

Here \( P_1(D) \) is a first order differential operator with bounded coefficients, i.e.,
\[
    \|P_1(D)u\|^2_{H^0(\Omega)} \leq K_1 \|u\|^2_{H^1(\Omega)}.
\]

Assume that our problem is weakly well posed in the generalized sense. Then the perturbed problem has the same property.

Proof. In the same way as in Theorem 1.8 we consider \( P_1(D)u \) as part of the forcing and choose \( \eta_0 \) and \( \alpha \) sufficiently large. Then the desired estimate follows.

\[
\square
\]

2. A SINGLE WAVE EQUATION

2.1. A necessary condition for well posedness

To derive necessary conditions we consider in this section the halfplane problem for the wave equation
\[
    u_{tt} = u_{xx} + u_{yy} + F(x, y, t), \quad x \geq 0, \quad -\infty < y < \infty, \quad t \geq 0
\]
(14)

with initial conditions, at \( t = 0 \),
\[
    u(x, y, 0) = f_1(x, y), \quad u_t(x, y, 0) = f_2(x, y)
\]

and one of four types of boundary conditions at \( x = 0, \quad -\infty < y < \infty \):

1. \( u_t = au_x + bu_y + g, \quad a, b \text{ real}, \quad |b| < 1, \quad a > 0. \)
2. \( u_x = ibu_y + g, \quad b \text{ real}, \quad b \neq 0, \quad |b| < 1. \)
3. \( u_x = g. \)
4. \( u_x = bu_y + g, \quad b \text{ real}, \quad b \neq 0. \)

The source \( F \) and the data \( f_j, g \) are compatible smooth functions with compact support. We are only interested in solutions with bounded \( L^2 \)-norm and therefore we assume
\[
    \int_{-\infty}^{\infty} \int_{0}^{\infty} |u(x, y, t)|^2 \, dx \, dy = \|u\|^2 < \infty \quad \text{for every fixed } t.
\]
(16)

We start with a test to find a necessary condition such that the problem is well posed.

Lemma 2.1. Let \( F = g = 0 \). The problem (14)–(15) is not well posed if we can find a nontrivial simple wave solution of type
\[
    u = e^{st+\omega y} \phi(x), \quad \|\phi(x)\| < \infty, \quad \text{Re } s > 0.
\]
(17)

Proof. If we have found such a solution, then
\[
    u_{\alpha} = e^{s_0 t+\omega \alpha y} \phi(\alpha x), \quad \alpha > 0.
\]
is also a solution for any \( \alpha > 0 \). Since \( \text{Re } s > 0 \), we can find solutions which grow arbitrarily fast exponentially.

\[
\square
\]
We shall now discuss whether there are such solutions. Introducing (17) into the homogeneous differential equation (14) and homogeneous boundary conditions (15) gives us

$$\varphi_{xx} - (s^2 + \omega^2) \varphi = 0, \quad ||\varphi|| < \infty.$$  

(18) is an ordinary differential equation with constant coefficients and boundary conditions

1) $s \varphi(0) = a \varphi_x(0) + b i \omega \varphi(0), \quad a, b \text{ real}, \quad |b| < 1, \quad a > 0.$
2) $\varphi_x(0) = -b \omega \varphi(0), \quad b \text{ real}, \quad b \neq 0, \quad |b| < 1.$
3) $\varphi_x(0) = 0.$
4) $\varphi_x(0) = b i \omega \varphi(0), \quad b \text{ real}, \quad b \neq 0.$

The general solution of (18) is of the form

$$\varphi(x) = \sigma_1 e^{\kappa x} + \sigma_2 e^{-\kappa x},$$  

(20)

where $\pm \kappa$ are the solutions of the characteristic equation

$$\kappa^2 - (s^2 + \omega^2) = 0, \quad \text{i.e.,} \quad \kappa = \sqrt{s^2 + \omega^2}.$$  

We fix the argument of $\sqrt{\cdot}$ by

$$-\pi < \arg(s^2 + \omega^2) \leq \pi, \quad \arg \sqrt{s^2 + \omega^2} = \frac{1}{2} \arg(s^2 + \omega^2).$$

From the general theory (also proved in Lemma A.5 in the appendix) we know that, there is a constant $\delta > 0$ such that

$$\text{Re} \kappa \geq \delta \text{ Re } s.$$  

Therefore $\varphi \in L^2$ if and only if $\sigma_1 = 0$. Introducing (20) into the boundary conditions gives us

1) $s = -a \kappa + i \omega b, \quad a, b \text{ real}, \quad |b| < 1, \quad a > 0.$
2) $\kappa = \omega b, \quad b \text{ real}, \quad b \neq 0, \quad |b| < 1.$
3) $\kappa = 0.$
4) $\kappa = -i \omega b, \quad b \text{ real}, \quad b \neq 0.$

Since, by assumption, $a > 0$ and $\text{Re } \kappa > 0$, there are no solutions of type (17) for the first kind of boundary condition. It is important to stress here that choosing the wrong sign for $a$ in the first type of boundary condition results into an ill posed problem and no solution can be computed. The second case in (21) implies

$$\omega^2 + s^2 = \omega^2 b^2, \quad \text{i.e.,} \quad s^2 = \omega^2 (b^2 - 1).$$

Thus there are no solutions of type (17) for $|b| < 1, \quad b \text{ real}$. As $\text{Re } \kappa > 0$ there are no solution of type (17) for the third boundary condition. Finally, since $\text{Re } \kappa > 0$ and $b$ is real, there are no simple wave solutions of type (17) for the fourth kind of boundary condition.

We have proved

**Theorem 2.2.** For the boundary conditions (15) there are no simple wave solutions of type (17) other than the trivial solution $u \equiv 0$.

Since (18) and (21) define eigenvalue problems, we can phrase the theorem also as
Theorem 2.3. The eigenvalue problems (18) and (21) have no eigenvalues with \( \text{Re} s > 0 \).

We shall now introduce the concept of generalized eigenvalues. For that purpose we write (21) in terms of normalized variables.

\[
s' = s / \sqrt{|s|^2 + \omega^2}, \quad \omega' = \omega / \sqrt{|s|^2 + \omega^2}, \quad \kappa' = \kappa / \sqrt{|s|^2 + \omega^2}.
\]

Definition 2.4. Let \( s' = i \xi'_0, \omega' = \omega'_0 \) be a fixed point and consider (18), (21) for \( s' = i \xi'_0 + \eta', \omega' = \omega'_0, \eta' > 0 \). \( (i \xi'_0, \omega'_0) \) is a generalized eigenvalue for a boundary condition if in the limit \( \eta' \to 0 \) the boundary condition is satisfied.

We now calculate the generalized eigenvalues. By Lemma A.7, there are no generalized eigenvalues for boundary conditions of type 1).

For boundary conditions of type 2), we need to consider

\[
\lim_{\eta' \to 0} \left( \sqrt{(i \xi'_0 + \eta')^2 + \omega'_0^2} - b \omega'_0 \right).
\]

As \( \text{Re} \kappa' \geq 0 \), there will be a generalized eigenvalue for boundary condition 2) if and only if \( b \omega'_0 > 0 \) and

\[
-\xi'_0^2 + \omega'_0^2 = b^2 \omega'_0^2, \quad \text{i.e.,} \quad \xi'_0 = \pm \sqrt{1 - b^2} \omega'_0.
\]

Since

\[
\kappa'_0 = \sqrt{-\xi'_0^2 + \omega'_0^2} = b \omega'_0 > 0,
\]

the corresponding eigenfunctions are

\[
u = e^{-|\omega_0|x} e^{i \omega_0(y \pm \sqrt{1 - b^2} t)}.
\]

They represent surface waves which decay exponentially in \( x \), i.e. in the normal direction away from the boundary. They are important phenomena in many applications (e.g. elastic wave equations).

For boundary conditions 3) and 4) \( \xi'_0, \omega'_0 \) must satisfy the relation

\[
\xi'_0 = \pm \sqrt{1 + b^2 \omega'_0}, \quad \kappa'_0 = -i \omega'_0 b,
\]

and where the sign in the first relation is chosen so that \( \xi'_0 b \omega'_0 < 0 \) (because \( \text{Re} \kappa' \geq 0 \)). The corresponding eigenfunction is

\[
u = e^{i \omega_0 (bx + y)} e^{\pm i \sqrt{1 + b^2} |\omega_0| t}.
\]

For boundary condition 4) \( (b \neq 0) \), they are oscillatory in \( x, y, t \). For boundary condition 3) \( (b = 0) \), they are constant normal to the boundary and they are called glancing waves. They are important physical phenomena (e.g. Maxwell’s equations).

We collect the results in

Theorem 2.5. There are no generalized eigenvalues for boundary conditions of type (1). For boundary condition (2), (3) and (4) the generalized eigenvalues are given by

\[\begin{align*}
2) \quad \xi'_0 &= \pm \sqrt{1 - b^2} \omega'_0, \quad \kappa'_0 = b \omega'_0 > 0. \\
3) \quad |\xi'_0| &= |\omega'_0|, \quad \kappa'_0 = 0. \\
4) \quad |\xi'_0| &= \sqrt{1 + b^2} |\omega'_0|, \quad \kappa'_0 = -i \omega'_0 b, \quad \xi'_0 b \omega'_0 < 0.
\end{align*}\]
2.2. Reduction to a first order system of pseudo-differential equations

The estimates obtained in this and subsequent sections are expressed in Fourier-Laplace transformed space. It is clear that all these estimates have their counterpart in physical space (such as the estimates in the definitions of section 1.1). To understand the relation between both types of estimates we refer to chapter 7.4 of [2] and chapter 10 of [3].

We consider (14)–(16) with homogeneous initial data. We Laplace transform the problem with respect to $t$, Fourier transform it with respect to $y$, and denote the dual variables by $s, \omega$, respectively. For $\Re s > 0$ we obtain

$$\hat{u}_{xx} = (s^2 + \omega^2)\hat{u} + \hat{F}, \quad \hat{u} = \hat{u}(x, \omega, s), \quad \hat{F} = \hat{F}(x, \omega, s), \quad 0 \leq x < \infty,$$

with one of the boundary conditions

1) $s\hat{u}_x = a\hat{u} + ib\omega\hat{u} + \hat{g},$
2) $\hat{u}_x = -b\omega\hat{u} + \hat{g},$
3) $\hat{u}_x = \hat{g},$
4) $\hat{u}_x = ib\omega\hat{u} + \hat{g},$ (23)

and $\|\hat{u}(\cdot, \omega, s)\|^2 < \infty$.

Introducing a new variable by

$$\hat{u}_x = \sqrt{|s|^2 + \omega^2} \hat{v},$$

we write the Fourier and Laplace transformed system as a first order system

$$\hat{u}_x = \sqrt{|s|^2 + \omega^2} M\hat{u} + \hat{F}_0.$$ (26)

Here

$$\hat{u} = \begin{pmatrix} \hat{u} \\ \hat{v} \end{pmatrix}, \quad M = \begin{pmatrix} 0 & 1 \\ \kappa'^2 & 0 \end{pmatrix}, \quad \hat{F}_0 = \frac{1}{\sqrt{|s|^2 + \omega^2}} \begin{pmatrix} 0 \\ \hat{F} \end{pmatrix},$$

with

$$\kappa' = \sqrt{(s')^2 + (\omega')^2}, \quad s' = \frac{s}{\sqrt{|s|^2 + \omega^2}}, \quad \omega' = \frac{\omega}{\sqrt{|s|^2 + \omega^2}}.$$

The eigenvalues $\mu$ of $M$ are $\mu_1 = -\kappa'$ and $\mu_2 = \kappa'$. The boundary conditions at $x = 0$ become

1) $s'\hat{v} = a\hat{u} + ib\omega'\hat{u} + g'$, $\quad a > 0, \quad |b| < 1,$
2) $\hat{v} = -b\omega'\hat{u} + g'$, $\quad |b| < 1, \quad b \neq 0,$
3) $\hat{v} = g'$, (27)
4) $\hat{v} = ib\omega'\hat{u} + g'$, $\quad b \text{ real}, \quad b \neq 0,$

with $g' = \hat{g}/\sqrt{|s|^2 + \omega^2}$.

Remark 2.6. We present in this and the following section the easiest way to obtain the estimates at the boundary and in the interior of the domain. To generalize these results to variable coefficients pseudo-differential theory is needed. The transformations $S$ and $T$ introduced below (see eqns. (29,44)) need to be smooth in the dual variables. The smoothness condition may fail only at the double root of $M$. In this case the Kreiss’ symmetrizer is used to get the estimates as explained in [1].

We shall now calculate the solution for the case when $F = 0$, and estimate it on the boundary.

The eigenvector of $M$ connected with $-\kappa'$ is given by

$$x = \begin{pmatrix} 1 \\ -\kappa' \end{pmatrix}.$$ (28)
The transformation
\[ S = \begin{pmatrix} 1 & \kappa' \\ -\kappa' & 1 \end{pmatrix} \] is, except for a trivial normalization, unitary and transforms \( M \) into upper triangular form, i.e.,
\[ S^{-1}MS = \begin{pmatrix} -\kappa' & d \\ 0 & \kappa' \end{pmatrix}, \quad d = \frac{1 + |\kappa'|^4}{1 + |\kappa'|^2}. \] (30)
Here \( S, S^{-1}, d \) are uniformly bounded and depend smoothly on \( \kappa' \).

Introducing a new variable by
\[ \begin{pmatrix} \hat{u} \\ \hat{v} \end{pmatrix} = S \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix} \] (31)
transforms (26) into
\[ \begin{pmatrix} \hat{u} \\ \hat{v} \end{pmatrix}_x = \begin{pmatrix} -\kappa & d\sqrt{|s|^2 + \omega^2} \\ 0 & \kappa \end{pmatrix} \begin{pmatrix} \hat{u} \\ \hat{v} \end{pmatrix}. \] (32)
As the solution is in \( L^2 \), we have \( \hat{v} = 0 \) and also \( \hat{u} = \tilde{u} \). Thus the boundary conditions become
\[ \begin{align*}
1) & \quad (s' + a\kappa' - ib\omega')\hat{u} = g', \\
2) & \quad (\kappa' - b\omega')\hat{u} = -g', \\
3) & \quad \kappa'\hat{u} = -g', \\
4) & \quad (\kappa' + ib\omega')\hat{u} = -g'.
\end{align*} \] (33)
By (21), these boundary conditions become singular exactly at the generalized eigenvalues.

**Remark 2.7.** From all the boundary conditions the first one is the most benign. By Lemma A.7 we obtain the estimate on the boundary
\[ |\hat{u}(0, \omega, s)|^2 \leq \text{const.} \frac{|s|^2 + \omega^2}{|\hat{g}(\omega, s)|^2}. \] (34)
In this case we gain a derivative on the boundary and the problem is boundary stable. According to the classical theory [1,2] the problem is *Strongly Well Posed in the Generalized Sense*. Moreover, the principle of localization holds and the problem can be generalized to variable coefficients and then to quasilinear equations. It is worth noticing here that away from generalized eigenvalues, i.e. when the coefficients on the left hand side of (33) are strictly away from zero, the estimate (34) holds also for boundary conditions 2), 3) and 4) and therefore the problem can be treated by the classical theory.

Because of the previous remark, we only need to study the estimates near the generalized eigenvalues. We have

**Theorem 2.8.** The problem (14)–(16) with \( F = 0 \) and \( f_1 = f_2 = 0 \) has a unique solution in \( L^2 \) which, Fourier-Laplace transformed, is given by
\[ \hat{u} = e^{-\kappa x}\tilde{u}(0, \omega, s), \quad \kappa = \sqrt{|s|^2 + \omega^2}. \] (35)
For the different boundary conditions sharp estimates follow. For boundary condition 1) and, “away” from generalized eigenvalues, for all other boundary conditions the problem is Boundary Stable and
\[ 1) \quad |\hat{u}(0, \omega, s)|^2 \leq \text{const.} \frac{|s|^2 + \omega^2}{|\hat{g}|^2}. \] (36)
Near generalized eigenvalues the estimates for boundary conditions 2), 3) and 4) are

\[ 2) \quad |\hat{u}(0, \omega, s)|^2 \leq \frac{\text{const.}}{\eta^2} |\hat{g}|^2, \]

\[ 3) \quad |\hat{u}(0, \omega, s)|^2 \leq \text{const.} \frac{|\hat{g}|^2}{|\kappa|^2} \leq \text{const.} \frac{|\hat{g}|^2}{\eta (|s|^2 + \omega^2)^{1/2}}, \tag{37} \]

\[ 4) \quad |\hat{u}(0, \omega, s)|^2 \leq \frac{\text{const.}}{\eta^2} |\hat{g}|^2, \]

and the problem is Weakly Boundary Stable.

Proof. Clearly, as \( \tilde{v} = 0 \) and \( \hat{u} = \tilde{u} \), (35) is the only solution to (32). We need to consider only a neighbourhood of the generalized eigenvalues \((i\xi_0', \omega_0').\) For the second boundary condition \( \xi_0' = \pm \sqrt{1 - b^2} \omega_0', \) i.e.,

\[ s' = i(\xi_0' + \tilde{\xi}') + \eta', \quad \eta' \geq 0, \quad \omega' = \omega_0' + \tilde{\omega}', \quad |\tilde{\xi}'| + |\tilde{\omega}'| + \eta' \ll 1. \]

Since \( \kappa' \neq 0 \) at \((i\xi_0', \omega_0').\) we can use Taylor expansion. A simple perturbation calculation shows that the worst estimate occurs for \( \xi' = \omega' = 0. \) In this case we have,

\[ |\kappa' - b \omega'| = \sqrt{-\xi_0'^2 + 2i \xi_0' \eta' + \eta'^2 + \omega_0'^2 - b \omega_0'} \]

\[ = \sqrt{b^2 \omega_0'^2 + 2i \xi_0' \eta' + \eta'^2 - b \omega_0'} \]

\[ \approx |b \omega_0' - b \omega_0' + i \xi_0' \eta'| \approx \frac{\sqrt{1 - b^2}}{|b|} \eta' \quad \text{if} \quad b \omega_0' > 0. \tag{38} \]

Thus we have

\[ |\hat{u}(0, \omega, s)|^2 \leq \text{const.} \frac{|\hat{g}'|^2}{\eta^2} = \text{const.} \frac{|\hat{g}|^2}{\eta^2}. \]

A similar perturbation calculation gives

\[ |\kappa' + i b \omega'| \approx \frac{\sqrt{1 + b^2}}{|b|} \eta' + O(\eta^2) \tag{39} \]

which gives, for the last boundary condition

\[ |\hat{u}(0, \omega, s)|^2 \leq \text{const.} \frac{|\hat{g}|^2}{\eta^2}. \]

For the third boundary condition on can do better. Lemma A.4 with \( b = 0 \), gives us

\[ |\hat{u}(0, \omega, s)|^2 \leq \text{const.} \left( \frac{|\hat{g}'|}{|\kappa'|} \right)^2 = \text{const.} \left( \frac{|\hat{g}|}{|\kappa|} \right)^2 \leq \frac{\text{const.} |\hat{g}|^2}{\eta (|s|^2 + \omega^2)^{1/2}}, \tag{40} \]

This proves the theorem. \( \square \)

**Theorem 2.9.** When \( f_1 = f_2 = 0 \) and \( F = 0. \) The unique solution to our problem, described in Theorem 2.8, satisfies the following interior estimates. For boundary condition 1) and, away from generalized eigenvalues, for boundary conditions 2), 3) and 4)

\[ ||\hat{u}||^2 \leq \frac{\text{const.}}{\eta} \frac{|\hat{g}|^2}{|s|^2 + \omega^2}. \tag{41} \]
Close to generalized eigenvalues, for the corresponding boundary conditions, we have

\[
2) \quad \|\tilde{u}\|^2 \leq \text{const.} \frac{|\gamma|^2}{\eta^2 (|s|^2 + \omega^2)^{1/2}} \\
3) \quad \|\tilde{u}\|^2 \leq \text{const.} \frac{|\gamma|^2}{\eta^{3/2} (|s|^2 + \omega^2)^{3/4}} \\
4) \quad \|\tilde{u}\|^2 \leq \text{const.} \frac{|\gamma|^2}{\eta^3 |s|^2 + \omega^2}.
\]

(42)

**Proof.** By Theorem 2.8 and Lemma A.2, the solution satisfies

\[\|\tilde{u}\|^2 \leq \frac{1}{\text{Re } \kappa} |\tilde{u}(0, \omega, s)|^2.\]

Since, by Lemma A.5, always \(\text{Re } \kappa \geq \delta_4 \eta\), we obtain from (35) that (41) is valid. 2) follows because, by Theorem 2.5, \(\text{Re } \kappa' \simeq b \omega_0'\) and then \(\text{Re } \kappa \geq \text{const. } \sqrt{|s|^2 + \omega^2}\). 3) follows from (40), Lemma A.6 and Lemma A.4, according to

\[\|\tilde{u}\|^2 \leq \text{const.} \frac{|\gamma|^2}{\eta |s|^2 + \omega^2} \leq \text{const.} \frac{|\gamma|^2}{\eta^{3/2} (|s|^2 + \omega^2)^{3/4}}.\]

(43)

Finally 4) corresponds to 4) of (37). This proves the theorem. \(\square\)

### 2.3. Estimates for homogeneous boundary data

We consider now the problem (26), (27) with \(g' = 0\) and treat only the cases 2), 3) and 4) where there are generalized eigenvalues (see Remark 2.7).

For \(\eta = \text{Re } s > 0\), the eigenvalues of \(M\) are distinct and therefore we can transform (26) to diagonal form by the transformation

\[T = \begin{pmatrix} 1 & \frac{1}{1 - \kappa'} \\ -\kappa' & 1 \end{pmatrix}, \quad T^{-1} = \frac{1}{2} \begin{pmatrix} 1 & -1/\kappa' \\ 1 & 1/\kappa' \end{pmatrix},\]

(44)

Let \(\tilde{u}, \tilde{v}\) be defined by

\[\begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix} = T \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix}.\]

(45)

Then, (26) becomes

\[\begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix}_x = \begin{pmatrix} -\kappa & 0 \\ 0 & \kappa' \end{pmatrix} \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix} + \frac{1}{2\kappa' \sqrt{|s|^2 + \omega^2}} \begin{pmatrix} -\hat{F} \\ \hat{F} \end{pmatrix},\]

(46)

with boundary conditions

\[
2) \quad (\kappa' - b \omega')\tilde{u}(0, \omega, s) = (\kappa' + b \omega')\tilde{v}(0, \omega, s).
3) \quad \tilde{u}(0, \omega, s) = \tilde{v}(0, \omega, s).
4) \quad (\kappa' + ib \omega')\tilde{u}(0, \omega, s) = (\kappa' - ib \omega')\tilde{v}(0, \omega, s).
\]

(47)

The equations (46) are decoupled and as \(\text{Re } \kappa > 0\), Lemma A.1 gives for all boundary conditions

\[
\|\tilde{v}(0, \omega, s)\|^2 \leq \frac{1}{8|\kappa'|^2 \text{Re } \kappa} \frac{\|\hat{F}\|^2}{|s|^2 + \omega^2} = \frac{1}{8|\kappa'|^2 \text{Re } \kappa' \sqrt{|s|^2 + \omega^2}} \frac{\|\hat{F}\|^2}{(|s|^2 + \omega^2)^{3/2}}.
\]

\[
\|\tilde{v}(0, \omega, s)\|^2 \leq \frac{1}{4|\kappa'|^2 \text{Re } \kappa'^2 \sqrt{|s|^2 + \omega^2}} = \frac{1}{4|\kappa'|^2 \text{Re } \kappa'^2 (|s|^2 + \omega^2)^{3/2}}.
\]

(48)

We use the boundary conditions to estimate \(\tilde{u}(0, \omega, s)\).
Theorem 2.5 tells us that \( \Re \kappa_0' \approx b \omega_0' > 0 \) in a neighborhood of the generalized eigenvalue connected with boundary condition 2). Therefore the perturbation calculation (38) gives us

\[
|\tilde{u}(0, \omega, s)|^2 = \left| \frac{\kappa' + b \omega'}{\kappa' - b \omega'} \right|^2 |\tilde{v}(0, \omega, s)|^2 \leq \frac{\text{const.}}{\eta^2} \frac{\|\tilde{F}\|^2}{(|s|^2 + \omega^2)^{3/2}} \leq \frac{\text{const.}}{\eta^2} \frac{\|\tilde{F}\|^2}{(|s|^2 + \omega^2)^{1/2}}. \tag{49}
\]

The interior estimate in this case follows from Lemma A.2, \( \Re \kappa = \Re \kappa' \sqrt{|s|^2 + \omega^2} \) and (49)

\[
\|\tilde{u}(\cdot, \omega, s)\|^2 \leq \frac{|\tilde{u}(0, \omega, s)|^2}{\Re \kappa} + \frac{\text{const.}}{(\Re \kappa)^2} \frac{\|\tilde{F}\|^2}{|s|^2 + \omega^2} \leq \frac{\text{const.}}{\eta^2} \frac{\|\tilde{F}\|^2}{|s|^2 + \omega^2}. \tag{50}
\]

Since the transformation \( T \) is bounded, (45) tells us that the estimates (48)–(50) are also valid for \( \hat{u}, \hat{v} \). Thus the problem is weakly well posed in the generalized sense.

For boundary condition 3), the generalized eigenvalue is \( \kappa' = 0 \) and therefore, for \( \Re s' > 0 \), we know only that \( \Re \kappa' \geq \delta \Re s' \). However, by Lemma A.6, we have a strong estimate for \( |\kappa| \Re \kappa \) and the estimates (48) become

\[
|\tilde{v}(0, \omega, s)|^2 \leq \frac{\text{const.}}{\eta^2} \frac{\|\tilde{F}\|^2}{\sqrt{|s|^2 + \omega^2}} \leq \frac{\text{const.}}{\eta^2} \frac{\|\tilde{F}\|^2}{|s|^2 + \omega^2},
\]

\[
\|\tilde{v}(\cdot, \omega, s)\|^2 \leq \frac{\text{const.}}{\eta^2} \frac{\|\tilde{F}\|^2}{|s|^2 + \omega^2}. \tag{51}
\]

By (47), the same estimate holds for \( \tilde{u}(0, \omega, s) \). By Lemma A.2, we obtain the interior estimate

\[
\|\tilde{u}(\cdot, \omega, s)\|^2 \leq \frac{\text{const.}}{\eta^2} \frac{\|\tilde{F}\|^2}{|s|^2 + \omega^2}. \tag{52}
\]

Since \( \hat{u}, \hat{v} \) satisfies the same estimates, the problem is weakly well posed in the generalized sense.

For boundary condition 4), the generalized eigenvalue is \( \kappa_0' = -i \omega_0' b, \ b \neq 0 \), is purely imaginary. Therefore, for \( \Re s' > 0 \), we can only use the estimate \( \Re \kappa' \geq \delta \Re s' \). Instead of (49) we obtain now

\[
|\tilde{u}(0, \omega, s)|^2 = \left| \frac{\kappa' - i \omega' b}{\kappa' + i \omega' b} \right|^2 |\tilde{v}(0, \omega, s)|^2 \leq \frac{\text{const.}}{\eta^2} \frac{\|\tilde{F}\|^2}{|s|^2 + \omega^2}.
\]

Again, the same estimates hold for \( \hat{u}, \hat{v} \). The estimates are sharp. Therefore we do not obtain the desired interior estimate and the problem is weakly unstable. We have proved

**Theorem 2.10.** For boundary conditions 2) and 3) our problem is weakly well posed in the generalized sense but not for boundary condition 4).

**Remark 2.11.** The estimates obtained for boundary conditions 2) and 3) tell us that \( \hat{u} \) gains one derivative with respect to the forcing in the interior of the domain and half a derivative on the boundary. The problem can be localized and generalized to variable coefficients and then to quasilinear equations. On the other hand, the estimates for the problem with boundary condition 4) show that not even a fractional derivative is gained with respect to the forcing. This, for a second order equation, means that one derivative of the solution is lost at every reflection on the boundary. The problem can not be localized. We do not pursue this problem but
illustrate below this bad type of behavior with a simple example: a first order system with a boundary condition equivalent to 4).

**An example**: Boundary reflection with loss or gain of differentiability. Consider a system of differential equations

\[ u_t = -u_x, \quad v_t = v_x, \quad 0 \leq x \leq 1, \quad t > 0, \]  
and boundary conditions

\[ u(0, t) = v_x(0, t), \quad v(1, t) = u_x(1, t). \]  
Then

\[ u = e^{\lambda(t-x)}u_0, \quad v = e^{\lambda(t+x)}v_0, \]  
is a solution of (53).

Introducing (55) into (54) gives us

\[ u_0 = \lambda v_0, \quad e^{\lambda}v_0 = -\lambda e^{-\lambda}u_0. \]  
Thus we obtain a solution of (53),(54) if

\[ e^{2\lambda} = -\lambda^2. \]  
Let

\[ \lambda = \lambda_n = \pi in + \tilde{\lambda}_n, \quad n = 1, 2, \ldots, \]  
then (57) becomes

\[ e^{2\lambda_n} = \pi^2 n^2 - 2\pi in \tilde{\lambda}_n - \tilde{\lambda}_n^2. \]  
(58) has a solution

\[ \tilde{\lambda}_n \approx \log \pi n. \]  
Therefore the solution (55) grows like

\[ e^{\lambda t} \approx e^{\pi int}, e^{t \log \pi n} = e^{\pi int} (\pi n)^t. \]  
If the initial data can be expanded into a Fourier series

\[ u(x, 0) = \sum_n e^{\lambda_n x} \hat{u}(\lambda_n), \]  
then (59) tells us that the solution loses more and more derivatives with time.

Now change the boundary conditions (54) to

\[ u_x(0, t) = v(0, t), \quad v_x(1, t) = u(1, t). \]  
Then we obtain, instead of (57),

\[ -\lambda u_0 = v_0, \quad \lambda e^{\lambda}v_0 = e^{-\lambda}u_0, \]  
i.e.,

\[ e^{2\lambda} = -\frac{1}{\lambda^2}. \]  
(60) Therefore there is no loss of derivatives.

Geometrically, the two sets of boundary conditions represents two different situations. In the first case any wave loses a derivative when reflected at the boundary. In the second case, it gains a derivative.
3. A MODEL PROBLEM AND NUMERICAL EXPERIMENTS

3.1. Two wave equations

In this section we consider two wave equations coupled through the boundary conditions.

\begin{align}
    u_{1tt} &= u_{1xx} + u_{1yy}, \\ 
    u_{2tt} &= u_{2xx} + u_{2yy}, \\
\end{align}

(61)
on the halfplane \( x \geq 0, -\infty < y < \infty \), for \( t \geq 0 \), with homogeneous initial conditions

\begin{align}
    u_i(x, y, 0) &= u_{it}(x, y, 0) = 0, \quad i = 1, 2, \\
    t &= 0,
\end{align}

(62)and boundary conditions at \( x = 0 \),

\begin{align}
    u_{1x} + b_1 u_{2y} &= g_1, \\ 
    u_{2x} + b_2 u_{1y} &= g_2, \quad x = 0.
\end{align}

(63)

Here \( b_1, b_2 \), are real and \( g_j = g_j(y, t) \), \( j = 1, 2 \), are smooth functions which are compatible with the initial data (for example, functions that vanish near \( t = 0 \)).

Fourier and Laplace transform lead to

\begin{align}
    \hat{u}_{1xx} - (\omega^2 + s^2) \hat{u}_1 &= 0, \\ 
    \hat{u}_{2xx} - (\omega^2 + s^2) \hat{u}_2 &= 0, \quad \Re s > 0.
\end{align}

(64)

Thus we obtain solutions that belong to \( L^2 \)

\begin{align}
    \hat{u}_1 = e^{st + i\omega y - \kappa x} \hat{u}_{10}, \\ 
    \hat{u}_2 = e^{st + i\omega y - \kappa x} \hat{u}_{20},
\end{align}

(65)

where

\[ \kappa = \sqrt{\omega^2 + s^2}, \quad \text{for } \Re s > 0. \]

We recall here that \( \Re \kappa > 0 \) when \( \Re s > 0 \). The transformed boundary conditions become

\begin{align}
    -\kappa \hat{u}_{10} + i \omega b_1 \hat{u}_{20} &= \hat{g}_1, \\ 
    i \omega b_2 \hat{u}_{10} - \kappa \hat{u}_{20} &= \hat{g}_2.
\end{align}

(66)

A simple calculation shows that (66) has a unique solution

\begin{align}
    \hat{u}_{10} &= -\kappa \hat{g}_1 + i \omega b_1 \hat{g}_2 / \kappa^2 + \omega^2 b_1 b_2, \\ 
    \hat{u}_{20} &= -\kappa \hat{g}_2 + i \omega b_2 \hat{g}_1 / \kappa^2 + \omega^2 b_1 b_2,
\end{align}

(67)

if and only if

\[ \Det \begin{pmatrix} -\kappa & i \omega b_1 \\ i \omega b_2 & -\kappa \end{pmatrix} = \kappa^2 + \omega^2 b_1 b_2 \neq 0. \]

(68)

There is an eigenvalue to the homogeneous problem (64), (66) with \( \hat{g}_1 = \hat{g}_2 = 0 \), if the homogeneous system (66) has a nontrivial solution. By (66), this is the case if

\[ \kappa^2 + \omega^2 b_1 b_2 = s^2 + \omega^2 (b_1 b_2 + 1) = 0. \]

(69)

There are five different situations:

1. \( b_1 b_2 < -1 \). By (69), there are eigenvalues \( s \) with \( \Re s > 0 \). Therefore our problem is not well posed.
2. \( b_1 b_2 = -1 \). Now \( s = 0 \) is a generalized eigenvalue. For \( s \neq 0 \) the solution (67) becomes

\begin{align}
    u_{10} &= -\frac{\kappa \hat{g}_1 + i \omega b_1 \hat{g}_2}{s^2}, \\ 
    u_{20} &= -\frac{\kappa \hat{g}_2 + i \omega b_2 \hat{g}_1}{s^2}.
\end{align}

(70)
In general, we can not expect that \( \hat{u}_{10} \), \( \hat{u}_{20} \) stay bounded for \( s \to 0 \). We need to assume that \( g_j = \hat{g}_{jtt} \) are the second time derivatives of smooth functions.

(3) \(-1 < b_1 b_2 < 0\). By (65),(69), we obtain generalized eigenvalues and eigenfunctions if \( s = \pm i \sqrt{1 + b_1 b_2} |\omega| \), \( \kappa = \sqrt{|b_1 b_2|} \omega \). The solution (67) is singular at the eigenvalues and \( \hat{u}_{10} \), \( \hat{u}_{20} \) have a first order pole. In physical space we obtain surface waves whose amplitudes become large for \( b_1 b_2 \to -1 \).

(4) \( b_1 b_2 = 0 \). Now \( s = \pm \omega \), \( \kappa = 0 \) determine the generalized eigenvalues and eigenfunctions. The behavior is the same as for the Neuman problem. We obtain glancing waves.

(5) \( b_1 b_2 > 0 \). In this case the generalized eigenvalues and eigenfunctions are determined by \( s = \pm i \sqrt{1 + b_1 b_2} \omega \), \( \kappa = \pm i \sqrt{b_1 b_2} \omega \). The eigenfunctions are oscillatory and the solution behaves like the solution of the wave equation in section 2.3 with boundary condition 4). Thus it is weakly unstable.

In summary we can state that the problem (61)–(63) is well posed for boundary conditions 2)–4) and weakly unstable for boundary condition 5). Also, there can be numerical difficulties if \( b_1 b_2 + 1 \) is zero or close to zero.

When we study the estimates for the problem in the cases 3) and 4) we get completely analogous estimates as the ones found for a single wave equation.

Consider the system
\[
\begin{align*}
    u_{1tt} &= u_{1xx} + u_{1yy} - F_1, & u_{2tt} &= u_{2xx} + u_{2yy} - F_2, \\
    u_{1x} + b_1 u_{2y} &= 0, & u_{2x} + b_2 u_{1y} &= 0, & x &= 0.
\end{align*}
\]
with boundary conditions
\[
\begin{align*}
    u_{1x} + b_1 u_{2y} &= 0, & u_{2x} + b_2 u_{1y} &= 0, & x &= 0.
\end{align*}
\]

Fourier and Laplace transform gives us
\[
\begin{align*}
    \hat{u}_{1xx} &= (s^2 + \omega^2)\hat{u}_1 + \hat{F}_1, & \hat{u}_{2xx} &= (s^2 + \omega^2)\hat{u}_2 + \hat{F}_2,
\end{align*}
\]
and define
\[
\begin{align*}
    \hat{u}_{1x} &= \sqrt{|s|^2 + \omega^2} \hat{v}_1, & \hat{u}_{2x} &= \sqrt{|s|^2 + \omega^2} \hat{v}_2.
\end{align*}
\]
Thus, the first order form of the problem becomes
\[
\begin{align*}
    \begin{pmatrix}
    \hat{u}_1 \\
    \hat{v}_1
    \end{pmatrix}_x &= \sqrt{|s|^2 + \omega^2} \begin{pmatrix}
    0 & 1 \\
    \kappa & 0
    \end{pmatrix} \begin{pmatrix}
    \hat{u}_1 \\
    \hat{v}_1
    \end{pmatrix} + \frac{1}{\sqrt{|s|^2 + \omega^2}} \begin{pmatrix}
    0 \\
    \hat{F}_1
    \end{pmatrix}, \\
    \begin{pmatrix}
    \hat{u}_2 \\
    \hat{v}_2
    \end{pmatrix}_x &= \sqrt{|s|^2 + \omega^2} \begin{pmatrix}
    0 & 1 \\
    \kappa & 0
    \end{pmatrix} \begin{pmatrix}
    \hat{u}_2 \\
    \hat{v}_2
    \end{pmatrix} + \frac{1}{\sqrt{|s|^2 + \omega^2}} \begin{pmatrix}
    0 \\
    \hat{F}_2
    \end{pmatrix}
\end{align*}
\]

with boundary conditions
\[
\begin{align*}
    \sqrt{|s|^2 + \omega^2} \hat{v}_{10} + i \omega b_1 \hat{v}_{20} &= 0, \\
    \sqrt{|s|^2 + \omega^2} \hat{v}_{20} + i \omega b_2 \hat{v}_{10} &= 0.
\end{align*}
\]

We transform (73) to diagonal form. Let
\[
\begin{align*}
    \begin{pmatrix}
    \hat{u}_j \\
    \hat{v}_j
    \end{pmatrix} &= \begin{pmatrix}
    1 & 1 \\
    -\kappa' & \kappa'
    \end{pmatrix} \begin{pmatrix}
    \hat{u}_j \\
    \hat{v}_j
    \end{pmatrix}, & j = 1, 2.
\end{align*}
\]
Then
\[
\begin{align*}
    \begin{pmatrix}
    \hat{u}_1 \\
    \hat{v}_1
    \end{pmatrix}_x &= \begin{pmatrix}
    0 & \kappa \\
    -\kappa & 0
    \end{pmatrix} \begin{pmatrix}
    \hat{u}_1 \\
    \hat{v}_1
    \end{pmatrix} + \frac{1}{\sqrt{|s|^2 + \omega^2}} \hat{F}_1, \\
    \begin{pmatrix}
    \hat{u}_2 \\
    \hat{v}_2
    \end{pmatrix}_x &= \begin{pmatrix}
    0 & \kappa \\
    -\kappa & 0
    \end{pmatrix} \begin{pmatrix}
    \hat{u}_2 \\
    \hat{v}_2
    \end{pmatrix} + \frac{1}{\sqrt{|s|^2 + \omega^2}} \hat{F}_2
\end{align*}
\]
with boundary conditions
\[
-\kappa \tilde{u}_{10} + i\omega b_1 \tilde{v}_{20} = -\kappa \tilde{v}_{10}, \\
i\omega b_2 \tilde{u}_{10} - \kappa \tilde{u}_{20} = -\kappa \tilde{v}_{20}.
\] (75)

In the same way as in section 2.3 we can determine \(-\kappa \tilde{v}_{10}, -\kappa \tilde{v}_{20}\) by solving the equations (74) for \(\tilde{v}_1, \tilde{v}_2\) and reduce the problem (71),(72) to the previous problem (61)–(63). Thus we obtain the same estimates.

### 3.2. Numerical experiments

In this section we numerically solve the strip problem for the scalar wave equation
\[
u_{tt} = u_{xx} + u_{yy} + F(x, y, t), \quad 0 \leq x \leq 1, \quad 0 \leq y \leq 1, \quad t \geq 0,
\] (76)
with 1-periodic solutions in the \(y\)-direction,
\[
u(x, y, t) = \nu(x, y + 1, t), \quad 0 \leq x \leq 1, \quad t \geq 0,
\] subject to initial conditions,
\[
u(x, y, 0) = f_1(x, y), \quad \nu_t(x, y, 0) = f_2(x, y), \quad 0 \leq x \leq 1, \quad 0 \leq y \leq 1,
\] (78)
and boundary conditions
\[
u_x - b \nu_y = g_0(y, t), \quad x = 0, \quad 0 \leq y \leq 1, \quad t \geq 0,
\] (79)
\[
u_x = g_1(y, t), \quad x = 1, \quad 0 \leq y \leq 1, \quad t \geq 0.
\] (80)

Here \(b\) is a constant. We are interested in the three cases \(b = 0, b\) real, and \(b\) purely imaginary, i.e.,
\[
b = i\beta, \quad \beta \text{ real}.
\]

To solve the latter problem using real arithmetic, we introduce real-valued functions \(\nu^{(1)}\) and \(\nu^{(2)}\) such that
\[
\nu = \nu^{(1)} + i\nu^{(2)}.
\] (81)

Inserting (81) into (76) leads to the system of scalar wave equations,
\[
u^{(1)}_{tt} = \nu^{(1)}_{xx} + \nu^{(1)}_{yy} + \text{Re} F(x, y, t), \quad 0 \leq x \leq 1, \quad 0 \leq y \leq 1, \quad t \geq 0,
\] (82)
\[
u^{(2)}_{tt} = \nu^{(2)}_{xx} + \nu^{(2)}_{yy} + \text{Im} F(x, y, t), \quad 0 \leq x \leq 1, \quad 0 \leq y \leq 1, \quad t \geq 0.
\] (83)

Boundary condition (79) can be written as
\[
u^{(1)}_x + \beta \nu^{(2)}_y = \text{Re} g_0(y, t), \quad x = 0, \quad 0 \leq y \leq 1, \quad t \geq 0,
\] (84)
\[
u^{(2)}_x - \beta \nu^{(1)}_y = \text{Im} g_0(y, t), \quad x = 0, \quad 0 \leq y \leq 1, \quad t \geq 0
\] (85)

which is of the form (63) with \(b_1 = \beta\) and \(b_2 = -\beta\).

We introduce a grid with grid size \(h = 1/(N - 1)\),
\[
x_j = (j - 1)h, \quad j = 0, 1, \ldots, N + 1, \quad y_k = kh, \quad k = 0, 1, \ldots, N.
\]
Time is discretized on a uniform grid with time step $\delta t > 0$, $t_n = n\delta t$, $n = 0,1,2,\ldots$ and we denote a grid function by 

$$v^n_{j,k} = v(x_j, y_k, t_n).$$

The standard divided difference operators are defined by 

$$D_{+x}v^n_{j,k} = \frac{v^n_{j+1,k} - v^n_{j,k}}{h}, \quad D_{-x}v^n_{j,k} = D_{+x}v^n_{j-1,k}, \quad D_{0x} = \frac{1}{2}(D_{+x} + D_{-x}),$$

with corresponding notations in the $y$- and $t$-directions.

Consider the difference approximation 

$$D_{+t}D_{-t}v^n_{j,k} = (D_{+x}D_{-x} + D_{+y}D_{-y})v^n_{j,k} + F(x_j, y_k, t_n), \quad (86)$$

subject to boundary conditions 

$$v^n_{j,0} - v^n_{j,N-1} = 0, \quad j = 0,1,\ldots,N+1, \quad (87)$$

$$v^n_{j,N} - v^n_{j,1} = 0, \quad j = 0,1,\ldots,N+1, \quad (88)$$

$$D_{0x}v^n_{1,k} - bD_{0y}v^n_{1,k} = g_0(y_k, t_n), \quad k = 1,2,\ldots,N-1, \quad (89)$$

$$D_{0x}v^n_{N,k} = g_1(y_k, t_n), \quad k = 1,2,\ldots,N-1, \quad (90)$$

for $n = -1,0,1,\ldots$, and initial conditions, 

$$v^0_{j,k} = f_1(x_j, y_k), \quad v^{-1}_{j,k} = f_2'(x_j, y_k), \quad j = 0,1,\ldots,N+1, \quad k = 0,1,\ldots,N. \quad (91)$$

When $b = 0$, the difference approximation (86)-(91) satisfies a discrete energy estimate, under the Courant time step restriction 

$$\delta t \leq Ch,$$

and is therefore stable. The energy method can not be used to show stability of the difference approximation when $b$ is non-zero and real, or purely imaginary. However, as we shall see below, our practical experience indicates that the approximation is stable also when $b$ is purely imaginary. When $b$ is non-zero and real, the continuous problem is weakly unstable. In this case, the difference approximation is convergent for short times.

To test the accuracy of the numerical solution, we choose the forcing functions $F$, $g_k$, and $f_k$ such that the exact solution becomes the traveling wave 

$$u_w(x, y, t) = \sin(2\pi(x - t))\sin(2\pi y).$$

For the case $b = i\beta$, we use the exact solution 

$$u_w^{(1)}(x, y, t) = \sin(2\pi(x - t))\sin(2\pi y),$$

$$u_w^{(2)}(x, y, t) = \cos(2\pi(x - t))\cos(2\pi y).$$

Table 1 shows the max norm of the error $u_w - v$ at different times for grid sizes $h = 10^{-2}, 5 \times 10^{-3}, 2.5 \times 10^{-3}$. All calculations used $\delta t = 0.5h$. The error decreases as $O(h^2)$ for all three values of $b$, both at time $t = 1$ and $t = 10$.

To illustrate how the $b$-coefficient in the boundary condition influences the solution, we study the evolution from an initial Gaussian pulse, 

$$f_1(x, y) = f_2'(x, y) = e^{-(x-0.5)^2/L^2-(y-0.5)^2/L^2}, \quad L = 0.03,$$
with homogeneous interior and boundary forcing functions, \( F = 0, g_0 = 0, g_1 = 0 \). In these calculations we use the grid size \( h = 5 \times 10^{-3} \) and time step \( \delta_t = 2.5 \times 10^{-3} \). The evolution between times \( t = 0.25 \) and \( t = 1.25 \) for the three cases \( b = 0 \), \( b = 0.5 \), and \( b = i \times 0.5 \) is shown in Figure 1. The solution initially propagates outwards towards the boundary (first column). Before the pulse reaches the boundary, the solutions are identical for all three cases. The middle column in Figure 1 shows the solutions after the initial pulse has reached the boundary, at \( t = 0.75 \). At this time, there are only minor differences between the three solutions. The influence of the boundary condition is becoming more obvious in the right column, corresponding to \( t = 1.25 \). While the differences between \( b = 0 \) and \( b = i \times 0.5 \) are still small and located near the left boundary, the case \( b = 0.5 \) has developed a structure near that boundary which is not present for \( b = 0 \), or \( b = i \times 0.5 \). For later times, the boundary structure develops into a diagonal streak which extends further and further into the domain until it gets reflected by the Neumann condition on the right boundary, see Figure 2. At later times, the reflected streak develops a new streak which grows into the domain in the same way. The solution is eventually dominated by these streaks which appear to propagate in the direction \( y + 0.5x \). Note that the propagation direction \( y + 0.5x \) is consistent with eigenfunction (22) since \( b = 0.5 \), see case 4) in section 2.1.

It is also interesting to monitor the max norm of the solution for longer times when \( b = 0.5 \), see Figure 3. Note that the solution grows exponentially with time, illustrating the weakly unstable nature of this boundary condition. Also note that the solution is slightly larger on the finer grid. This behavior agrees with the predicted exponential growth proportional to \(|\omega|^t\), because higher values of \(|\omega|\) are captured on the finer grid. Note, however, that this growth is not due to numerical instabilities because the accuracy test shows second order convergence, at least up to \( t = 10 \), see Table 1.

To more clearly see the difference between the cases \( b = 0 \) and \( b = i \beta \) we take \( F = 0, g_0 = g_1 = 0 \) and change the initial data to trigger a surface wave,

\[
f_1(x, y) = u_\text{s}(x, y, 0), \quad f_2^i(x, y) = u_\text{s}(x, y, -\delta_t),
\]

where

\[
u_\text{s}(x, y, t) = e^{-|\beta\omega_0| x} \left[ \cos \left( \omega_0 (y - \sqrt{1 - \beta^2} t) \right) + i \sin \left( \omega_0 (y - \sqrt{1 - \beta^2} t) \right) \right], \quad \beta \omega_0 > 0. \tag{92}
\]

This wave decays exponentially away from the \( x = 0 \) boundary with a harmonic oscillation in \( y \), see Figure 4. The surface wave propagates in the positive \( y \)-direction with a wave speed proportional to \( \sqrt{1 - \beta^2} \). As \( \beta \to 0 \), the surface wave decays slower and slower in the \( x \)-direction. In the limit \( \beta = 0 \), the amplitude of the wave is constant in \( x \) which corresponds to one-dimensional wave propagation in the \( y \)-direction, consistent with the limiting boundary condition \( u_\text{s} = 0 \). There are no numerical difficulties in this limit.

The case \(|\beta| \to 1 \) is more difficult to solve numerically. Here we study \( 0.5 \leq \beta < 1 \) and we use (92) as an approximation of the exact solution \( u_\text{s} \) is only exponentially small at \( x = 1 \) and does not exactly satisfy the boundary condition at that boundary). To make sure the amplitude of the surface wave is negligible at the

Table 1. Max error in the solution as function of the grid size with a traveling wave exact solution.
Figure 1. The solution at times $t = 0.25$ (left column), $t = 0.75$ (middle column), and $t = 1.25$ (right column) for $b = 0$ (top row), $b = 0.5$ (middle row), and $b = i 0.5$ (bottom row). The bottom row is showing the real part of the solution ($\hat{u}^{(1)}$).

For $x = 1$ boundary, we choose

$$\omega_0 = 8\pi, \quad e^{-|\beta\omega_0|} = e^{-4\pi} \approx 3.48 \times 10^{-6}, \quad \beta = 0.5.$$ 

In Table 2 we show the max norm of the error $u_s - v$ for different values of $\beta$. The case $\beta = 0.5$ shows second order convergence, both at time $t = 1$ and $t = 10$. As can be expected in wave propagation problems, the error is dominated by the phase error, which explains why it is about 10 times larger at $t = 10$ compared to $t = 1$. For $\beta = 0.9$, the error still converges to second order accuracy at time $t = 1$, but shows an unexpected pattern at time $t = 10$. Here the error is larger for the intermediate grid size $h = 5 \times 10^{-3}$ than for the coarse grid size $h = 10^{-2}$. This behavior is explained by studying the time history of the error, see Figure 5. For $h = 10^{-2}$, the max error occurs at $t \approx 5.5$ when the numerical solution is about 180 degrees out of phase with the exact solution. At later times the error in the numerical solution decreases because it is between 180 and 360 degrees out of phase. The grid with $h = 5 \times 10^{-3}$ is barely fine enough to capture the solution at time $t = 10$ because the phase error exceeds 90 degrees. As a result we don’t see the expected second order convergence when the grid is refined to $h = 2.5 \times 10^{-3}$. However, the error at $t = 10$ is about 10 times larger than at $t = 1$ for the finest grid, which indicates that this resolution is adequate for $\beta = 0.9$. The situation is even more dire for
Figure 2. The solution of the weakly unstable case \((b = 0.5)\) at times \(t = 2.5\) to \(t = 4.5\) in increments of 0.25, starting in the top left sub-figure and progressing row-wise to the bottom right sub-figure, e.g. \(t = 2.75\) is in the middle column of the top row.

Figure 3. The max norm of the solution for \(0 \leq t \leq 20\) for the case \(b = 0.5\), starting from a Gaussian pulse. The blue dots correspond to grid size \(h = 10^{-2}\) and the red crosses have \(h = 5 \times 10^{-3}\).

\(\beta = 0.99\). Here the errors at time \(t = 1\) show a similar behavior as at \(t = 10\) for \(\beta = 0.9\), so only the finest grid provides adequate resolution at \(t = 1\). At \(t = 10\), the error displays a completely erratic behavior with the
Figure 4. The real part of the initial data for the surface wave with $\beta = 0.5$ and $\omega_0 = 8\pi$.

largest error for the finest grid. An even finer grid would be necessary to obtain an accurate solution at $t = 10$, when $\beta = 0.99$.

\[
\begin{array}{|c|c|c|c|}
\hline
\text{Case} & h & \|u_s - v\|_\infty(t = 1) & \|u_s - v\|_\infty(t = 10) \\
\hline
\beta = 0.5 & 1 \times 10^{-2} & 2.44 \times 10^{-2} & 2.38 \times 10^{-1} \\

& 5 \times 10^{-3} & 5.20 \times 10^{-1} & 1.81 \times 10^{-1} \\
& 2.5 \times 10^{-3} & 1.44 \times 10^{-1} & 1.47 \times 10^{0} \\
\hline
\end{array}
\]

Table 2. Max error in the solution as function of the grid size when the exact solution is the surface wave $u_s(x, y, t)$.

So why is it so hard to calculate an accurate numerical solution as $|\beta| \to 1$? The spatial resolution in terms of grid points per wave length only depends on $\omega_0$. With $\omega_0 = 8\pi$, the wave length is $1/4$ and grid sizes $h = 10^{-2}$, $5 \times 10^{-3}$, $2.5 \times 10^{-3}$ correspond to 25, 50, and 100 grid points per wave length, respectively. The exponential decay in the $x$-direction only depends weakly on $\beta$ and never exceeds $e^{-|\omega_0|\varepsilon}$ for $\beta < 1$. Hence the solution varies on the same length scale in the $x$- and $y$-directions. Furthermore, the temporal resolution in terms of time steps per period only improves as $|\beta| \to 1$ because the wave speed goes to zero in this limit. We conclude that the numerical difficulties are not due to poor resolution of the solution.
To further analyze the cause of the poor accuracy in the numerical solution for $|\beta| \to 1$, we decompose the
problem (76)-(80) into two parts,
\[
u(x, y, t) = U(x, y, t) + u'(x, y, t),
\]
such that $U$ satisfies a doubly periodic problem on an extended domain,
\[
U_{tt} = U_{xx} + U_{yy} + \tilde{F}(x, y, t), \quad -1 \leq x \leq 2, \ 0 \leq y \leq 1, \ t \geq 0,
\]
subject to initial conditions,
\[
U(x, y, 0) = \tilde{f}_1(x, y), \quad U_t(x, y, 0) = \tilde{f}_2(x, y), \quad -1 \leq x \leq 2, \ 0 \leq y \leq 1,
\]
and periodic boundary conditions
\[
U(x, y, t) = U(x + 1, y, t), \quad -1 \leq x \leq 2, \ t \geq 0,
\]
\[
U(x, y, t) = U(x + 3, y, t), \quad 0 \leq y \leq 1, \ t \geq 0.
\]
The interior forcing function and the initial data can be smoothly extended to become 3-periodic in the $x$-
direction, without changing them on the original domain,
\[
\tilde{F}(x, y, t) = F(x, y, t), \quad \tilde{f}_k(x, y) = f_k(x, y), \quad 0 \leq x \leq 1, \ 0 \leq y \leq 1, \ t \geq 0.
\]
The problem for $U$ is independent of the $b$-coefficient in the boundary condition and can easily be solved
numerically.

The difference $u' = u - U$ satisfies the scalar wave equation (76)-(80) with homogeneous interior forcing,
homogeneous initial data, but inhomogeneous boundary conditions,
\[
\begin{align*}
u'_x - b u'_y &= g'_0(y, t) \quad x = 0, \ 0 \leq y \leq 1, \ t \geq 0, \\
u'_x &= g'_1(y, t) \quad x = 1, \ 0 \leq y \leq 1, \ t \geq 0.
\end{align*}
\]
(93) \hspace{1cm} (94)

The boundary forcing functions depend on $U$ according to
\[
\begin{align*}
g'_0(y, t) &= g_0(y, t) - (U_x(0, y, t) - b U_y(0, y, t)), \quad 0 \leq y \leq 1, \ t \geq 0, \\
g'_1(y, t) &= g_1(y, t) - U_x(1, y, t), \quad 0 \leq y \leq 1, \ t \geq 0.
\end{align*}
\]

The corresponding half-plane problems were analyzed in section 2.2. The accuracy problems are unlikely to
arise from the Neumann boundary condition at $x = 1$ since it is independent of the $b$-coefficient. However, the
half-plane problem subject to (93) satisfies the estimates of Theorem 2.8. Here, \( b = i \beta \) corresponds to case 2), and estimate (38) shows that the Laplace-Fourier transform of \( u' \) satisfies

\[
|\hat{u}'(0, \omega, s)|^2 \leq \frac{C \beta^2}{1 - \beta^2} \frac{|\hat{g}_0|^2}{\eta^2}, \quad \text{Re} \, s = \eta > 0,
\]

for \((\omega, s)\) in the vicinity of the generalized eigenvalue \( s_0 = \pm i \sqrt{1 - \beta^2} \omega_0 \). In general, the solution becomes unbounded as \(|\beta| \to 1\). The truncation error terms which perturb the numerical solution are therefore amplified by a factor \(1/\sqrt{1 - \beta^2}\), which explains the poor accuracy in the numerical solution as \(|\beta| \to 1\).

For boundary data \( g_0(y, t) \) which have a Laplace-Fourier transform that can be written as

\[
\hat{g}_0(\omega, s) = s\hat{G}(\omega, s),
\]

estimate (95) becomes

\[
|\hat{u}'(0, \omega, s)|^2 \leq \frac{C \beta^2}{1 - \beta^2} \frac{|s|^2|\hat{G}|^2}{\eta^2} \approx \frac{C \beta^2}{|s_0|^2/\omega_0^2} \frac{|s_0|^2|\hat{G}|^2_{\omega_0}}{\eta^2} = C/\beta^2 \omega_0^2 \frac{|\hat{G}|^2_{\omega_0}}{\eta^2}.
\]

Hence the \(|\beta| \to 1\) singularity cancels out and the solution is bounded independently of \(\beta\). The factor ‘s’ on the Laplace transform side corresponds to a time-derivative on the un-transformed side. Hence, the solution is bounded independently of \(\beta\) if the boundary forcing can be written as a time-derivative of a function with bounded Laplace-Fourier transform,

\[
g_0(y, t) = G_1(y, t), \quad G(y, 0) = 0, \quad \left| \int_{y=0}^{1} \int_{t=0}^{\infty} e^{-2\pi i \omega y} e^{-\omega t} G(y, t) \, dt \, dy \right| < \infty, \quad \text{Re} \, s \geq 0.
\]

The latter condition is satisfied if \(G(y, t)\) is in \(L^1\), i.e.,

\[
\int_{y=0}^{1} \int_{t=0}^{\infty} |G(y, t)| \, dt \, dy < \infty. \tag{96}
\]

To test this theory numerically, we use a homogeneous interior forcing \((F = 0)\) and homogeneous initial conditions \((f_1 = f_2 = 0)\), homogeneous forcing on the \(x = 1\) boundary \((g_1 = 0)\), and consider three different forcing functions on the \(x = 0\) boundary: \(g_0^{(1)}(y, t) = G(y, t)\), \(g_0^{(2)}(y, t) = G_1(y, t)\), and \(g_0^{(3)}(y, t) = G_{tt}(y, t)\). Here we choose \(G(y, t)\) to trigger a surface wave:

\[
G(y, t) = u_s(0, y, t) e^{-\left((t/t_0 - 7)^2\right)}, \quad t_0 = 0.2,
\]

where \(u_s\) is defined by (92). The Gaussian pulse \(e^{-((t/t_0 - 7)^2)}\) decays exponentially fast away from its center at \(t = 7t_0\). For example, it equals \(1.23 \times 10^{-4}\) at \(t = 7t_0 \pm 3t_0\), and \(5.24 \times 10^{-22}\) at \(t = 7t_0 \pm 7t_0\). The function \(G(y, t)\) satisfies (96), so our theory predicts that boundary forcings \(g_0^{(2)}\) and \(g_0^{(3)}\) should give solutions that are bounded independently of \(\beta\). However, the time-integral of a Gaussian pulse is the error-function (erf), so the boundary forcing \(g_0^{(1)}\) does not satisfy (96).

In the numerical calculations we take \(\omega_0 = 8\pi\) and study the cases \(\beta = 0.5\), \(\beta = 0.9\), and \(\beta = 0.99\). The grid size and time step are \(h = 2.5 \times 10^{-3}\) and \(\delta t = 0.5\). The max norm of the solution as function of time is shown in Figure 6. The case \(g_0^{(1)} = G\) in the top sub-figure illustrates the general case where the solution grows as \(|\beta| \to 1\). Note that estimate (95) predicts the solution to grow like \(\beta/\sqrt{1 - \beta^2}\), which means that the solution should be about 3.5 times larger for \(\beta = 0.99\) than \(\beta = 0.9\). In the numerical calculation, the max norm of the solution grows from about 0.75 for \(\beta = 0.9\) to 3.75 for \(\beta = 0.99\), which is slightly faster than predicted by theory.
Figure 6. The max norm of the solution as function of time for the boundary forcing functions $g_0^{(1)} = G$ (top), $g_0^{(2)} = G_t$ (middle), and $g_0^{(3)} = G_{tt}$ (bottom). In each figure, the green, blue, and red curves correspond to $\beta = 0.5$, $\beta = 0.9$, and $\beta = 0.99$, respectively. The case $g_0^{(3)} = G_{tt}$ in the bottom sub-figure shows the opposite situation when the solution decays as $\beta \to 1$ because the forcing function is a second time-derivative of a function with bounded $L^1$ norm, corresponding to an $s^2$ factor on the Laplace transform side. The intermediate case $g_0^{(2)} = G_t$ is shown in the middle sub-figure. Here the solution grows between $\beta = 0.9$ and $\beta = 0.99$, but not as fast as for $g_0^{(1)}$. To more closely study the behavior near $\beta = 1$, we take $\beta = 0.995$, 0.999 and 0.9997 corresponding to $\sqrt{1-\beta^2} \approx 0.0998$, 0.0447 and 0.0244, respectively. To properly resolve the solution we here use an extra fine grid with $h = 1.25 \times 10^{-3}$ and $\delta_t = 0.5h$. The max norm of the solutions, shown in Figure 7, reveal that the solution indeed stays bounded independently of $\beta$, confirming our theory also for boundary forcing $g_0^{(2)} = G_t$.

4. Second order systems of equations

4.1. The Cauchy problem

We consider the Cauchy problem for the system of the introduction

$$ u_{tt} = P_0(D)u + F, \quad t \geq 0, \ x \in \mathbb{R}^r: \ -\infty < x_j < \infty, \ j = 1, 2, \ldots r $$

(97)
Figure 7. The max norm of the solution as function of time for the boundary forcing function $g_0^{(2)} = G_t$ for $\beta = 0.995$ (blue/dots), $\beta = 0.999$ (red/diamonds) and $\beta = 0.9997$ (black/plusses).

were

$$P_0(D) = A_1 D_1^2 + \sum_{j=2}^r B_j D_j^2.$$  \hspace{1cm} (98)

$A_1 = A_1^* > 0$, $B_j = B_j^* > 0$, are positive definite symmetric $n \times n$ matrices and $u$ is a vector valued function with $n$ components.

At $t = 0$ we give initial data

$$u(x, 0) = f_1(x), \quad u_t(x, 0) = f_2(x).$$ \hspace{1cm} (99)

Also, $F, f_1, f_2$ are smooth functions with compact support.

We want to show that the problem is well posed. Let $F \equiv 0$ and Fourier transform the problem with respect to $x$. We obtain

$$\ddot{u}(\omega, 0) = \hat{f}_1(\omega), \quad \dot{u}_t(\omega, 0) = \hat{f}_2(\omega),$$

Introducing a new variable

$$\dot{u}_t = \hat{F}^{1/2} \hat{v},$$

gives us

$$\begin{pmatrix} \dot{\hat{u}} \\ \dot{\hat{v}} \end{pmatrix}_t = \begin{pmatrix} 0 & \hat{F}_0^{1/2} \\ -\hat{F}_0^{1/2} & 0 \end{pmatrix} \begin{pmatrix} \hat{u} \\ \hat{v} \end{pmatrix}.$$  

Therefore we obtain

$$\frac{\partial}{\partial t} (|\hat{u}|^2 + |\hat{v}|^2) = 0,$$

i.e.

$$||\hat{u}(\cdot, t)||^2 + ||\hat{v}(\cdot, t)||^2 = ||\hat{u}(\cdot, 0)||^2 + ||\hat{v}(\cdot, 0)||^2.$$  

This energy estimate shows that the Cauchy problem is well posed.
4.2. The resolvent equation

Consider the Cauchy problem for the inhomogeneous system (97) with \( F(x,t) \in C_0^\infty \) and with homogeneous initial data \( f_1 = f_2 = 0 \).

\[
  u_{tt} = P_0(D)u + F. \tag{100}
\]

Fourier transform with respect to \( x \) and Laplace transform with respect to time gives us the resolvent equation

\[
  \left( s^2 I + |\omega|^2 \hat{P}_0(\omega') \right) \hat{u} = \hat{F}, \quad s = i\xi + \eta, \ \eta > 0, \ \omega' = \omega/|\omega|. \tag{101}
\]

Since \( P_0 = P_0^* > 0 \), there is a unitary transformation which transforms (101) to diagonal form

\[
  \left( s^2 + |\omega|^2 \mu_j \right) \hat{u}_j = \hat{F}_j, \quad j = 1, 2, \ldots, n,
\]

i.e.,

\[
  (s + i|\omega|\sqrt{\mu_j})(s - i|\omega|\sqrt{\mu_j})u_j = \hat{F}_j.
\]

Without restriction we can assume that \( \xi > 0 \). Then

\[
  |s + i|\omega|\sqrt{\mu_j}| = \sqrt{\xi + |\omega|\sqrt{\mu_j}}^2 + \eta^2 \geq \sqrt{|s|^2 + |\omega|^2 \mu_j},
\]

\[
  |s - i|\omega|\sqrt{\mu_j}| = \sqrt{\xi - |\omega|\sqrt{\mu_j}}^2 + \eta^2 \geq \eta = \text{Re } s.
\]

Therefore

\[
  |\hat{u}_j| \leq \frac{|\hat{F}_j|}{\sqrt{|s|^2 + |\omega|^2 \mu_j} \text{Re } s}.
\]

Choosing \( \text{Im } s = i|\omega|\sqrt{\mu_j} \) shows that the estimate is sharp.

We have proved

**Theorem 4.1.** There is a constant \( K \) which does not depend on \( \omega \) such that the resolvent estimate

\[
  |\hat{u}(\omega, s)| \leq \frac{K|\hat{F}|}{\sqrt{|s|^2 + |\omega|^2} \text{Re } s} \tag{102}
\]

holds.

The last estimate shows that we ‘gain’ one derivative, i.e., if the forcing \( \in H^p \), then the solution \( \in H^{p+1} \). Therefore we can prove that the Cauchy problem is stable against lower order perturbations.

**Theorem 4.2.** Consider the Cauchy problem with homogeneous initial data for

\[
  u_{tt} = (P_0(D) + P_1(D)) u + F.
\]

Here \( P_1(D) \) represents a general first order operator. There is an \( \eta_0 > 0 \) such that the estimate (102) holds for \( \eta = \text{Re } s > \eta_0 \).

**Proof.** We consider \( P_1(D)u \) as part of the forcing. Then (102) gives us

\[
  |\hat{u}(\omega, s)| \leq \frac{K}{\text{Re } s} \frac{|P_1(\alpha, s)\hat{u}|}{\sqrt{|s|^2 + |\omega|^2}} + \frac{K}{\text{Re } s} \frac{|\hat{F}|}{\sqrt{|s|^2 + |\omega|^2}}.
\]
Since \( \frac{|P(i\omega,s)|}{\sqrt{|s|^2 + |\omega|^2}} \) is uniformly bounded, we choose \( \eta_0 \) such that

\[
K \frac{|P(i\omega,s)\hat{u}|}{\eta_0 \sqrt{|s|^2 + |\omega|^2}} \leq \frac{1}{2} |\hat{u}(\omega,s)|.
\]

Then the desired estimate follows. \( \square \)

We can write the resolvent equation also as a first order system. We Fourier transform (100) with respect to \( x_- = (x_2, \ldots, x_r) \) and Laplace transform it with respect to \( t \). Then we obtain

\[
A_1 D_2^2 \hat{u} = (s^2 I + B(\omega_-)) \hat{u} - \hat{F}, \quad B(\omega_-) = \sum_{j=2}^r B_j \omega_j^2.
\] (103)

Since \( A_1 > 0 \), there is a constant \( \sigma > 0 \) such that \( A_1 = A_1^* \geq \sigma I > 0 \). Introducing a new variable by

\[
A_1 D_1^2 \hat{v} = \sqrt{|s|^2 + |\omega_-|^2} \hat{v},
\]

we obtain the first order system

\[
D_1 \left( \begin{array}{c} \hat{u} \\ \hat{v} \end{array} \right) = M(s,\omega_-) \left( \begin{array}{c} \hat{u} \\ \hat{v} \end{array} \right) + \frac{1}{\sqrt{|s|^2 + |\omega_-|^2}} \left( \begin{array}{c} 0 \\ -A_1^{-1} \hat{F} \end{array} \right),
\] (104)

where

\[
M = M(s,\omega_-) = \left( \begin{array}{cc} 0 & \frac{A_1^{-1}(s^2 I + B(\omega_-))}{\sqrt{|s|^2 + |\omega_-|^2}} \\ \frac{A_1^{-1}(s^2 I + B(\omega_-))}{\sqrt{|s|^2 + |\omega_-|^2}} & 0 \end{array} \right).
\]

The eigenvalues \( \kappa \) of \( M \) are solutions of

\[
A_1 \kappa^2 \varphi_0 = (B(\omega_-) + s^2 I) \varphi_0.
\] (105)

**Lemma 4.3.** For \( \text{Re} \, s > 0 \), there are no \( \kappa_j \) with \( \text{Re} \, \kappa_j = 0 \). Also, there are exactly \( n \) eigenvalues, counted according to their multiplicity with \( \text{Re} \, \kappa < 0 \) and, therefore, \( n \) eigenvalues with \( \text{Re} \, \kappa > 0 \).

**Proof.** Assume there exists a \( \kappa = i\omega_1 \) which is purely imaginary. Then, by (101),

\[
\left( s^2 I - \hat{P}_0(i\omega_1, i\omega_-) \right) \varphi_0 = 0
\] (106)

has a nontrivial solution, i.e., \( s^2 \) is an eigenvalue of \( \hat{P}_0(i\omega) \). \( \hat{P}_0(i\omega) < 0 \) implies that \( s^2 \) is real and negative which is a contradiction with \( \text{Re} \, s > 0 \).

The solutions of (105) are continuous functions of \( \omega_- \). Therefore the number of \( \kappa \) with \( \text{Re} \, \kappa < 0 \) does not depend on \( \omega_- \) and we can assume that \( \omega_- = 0 \). Then (105) reduces to

\[
(s^2 I - A_1 \kappa^2) \varphi_0 = 0.
\] (107)

Since, by assumption, \( A_1 \) has positive eigenvalues \( \mu_j \) and a complete system of eigenvectors, we can transform (107) into \( n \) scalar equations

\[
(s^2 - \mu_j \kappa^2) u_j = 0, \quad j = 1, 2, \ldots, n,
\]

i.e.,

\[
\kappa = \pm s/\sqrt{\mu_j}, \quad \mu_j > 0, \quad j = 1, 2, \ldots, n, \quad \text{Re} \, s > 0.
\]

This proves the lemma. \( \square \)
By Schur’s lemma, there exists a unitary transformation $U = U(s, \omega_-)$ such that

$$U^*(s, \omega_-) M(s, \omega_-) U(s, \omega_-) = \begin{pmatrix} M_{11} & M_{12} \\ 0 & M_{22} \end{pmatrix},$$

where the eigenvalues $\kappa_{j1}, \kappa_{j2}$ of $M_{11}$ and $M_{22}$ satisfy $\text{Re} \kappa_{j1} < 0, \text{Re} \kappa_{j2} > 0$, respectively, for $\text{Re} s > 0$. Clearly, the transformed equation (104) can be solved uniquely for $\text{Re} s > 0$.

Using (102), we shall now derive estimates for the solutions of (104). To accomplish this we consider a more general forcing. We replace

$$\frac{1}{\sqrt{|s|^2 + |\omega_-|^2}} \begin{pmatrix} 0 \\ A_1^{-1} \hat{F} \end{pmatrix} \text{ by } \begin{pmatrix} \hat{F}_1 \\ \hat{F}_2 \end{pmatrix}, \quad \hat{F}_j = \hat{F}_j(x_1, \omega_-, s).$$

We Fourier transform (104) with respect to $x_1$ and consider

$$i \omega_1 \hat{u} = \sqrt{|s|^2 + |\omega_-|^2} \hat{v} - \hat{F}_1, \quad i \omega_1 \hat{v} = A_1^{-1} \left( s^2 I + B(\omega_-) \right) \hat{u} - \hat{F}_2.$$

Eliminating $\hat{v}$ gives us

$$\left( s^2 I + |\omega|^2 \hat{P}_0(\omega') \right) \hat{u} = i \omega_1 A_1 \hat{F}_1 + \sqrt{|s|^2 + |\omega_-|^2} A_1 \hat{F}_2.$$

Therefore, by (102), we obtain the estimate

$$|\hat{u}(-s, s)| \leq K \left| \frac{i \omega_1 \hat{F}_1 + \sqrt{|s|^2 + |\omega_-|^2} \hat{F}_2}{|A_1^{-1} \left( s^2 I + B(\omega_-) \right)|} \right| \leq K \left| \frac{|\hat{F}_1| + |\hat{F}_2|}{\text{Re} s} \right|, \quad \hat{F}_j = \hat{F}_j(\omega_1, \omega_-, s).$$

Eliminating $\hat{u}$, we obtain the same estimate for $\hat{v}$. Therefore we have proved

**Lemma 4.4.** There exists a constant $K > 0$ such that, for all $\omega_1, \omega_-, s$,

$$\left| \left( M(s, \omega_-) - i \omega_1 I \right)^{-1} \right| \leq \frac{2K}{\text{Re} s} \quad \text{(108)}$$

In particular, the eigenvalues $\kappa$ of $M(s, \omega_-)$ satisfy

$$|\text{Re} \kappa| \geq \frac{\text{Re} s}{2K}. \quad \text{(109)}$$

Using scaled variables

$$s' = s/\sqrt{|s|^2 + |\omega_-|^2}, \quad \omega' = \omega/\sqrt{|s|^2 + |\omega_-|^2}, \quad M'(s', \omega') = \begin{pmatrix} 0 \\ A_1^{-1} \left( s'^2 I + \beta(\omega_-) \right) \end{pmatrix},$$

we can write (108),(109) in the form

$$\left| \left( M'(s', \omega') - i \omega'_1 I \right)^{-1} \right| \leq \frac{2K}{\text{Re} s'}, \quad |\text{Re} \kappa'| \geq \frac{\text{Re} s'}{2K}. \quad \text{(110)}$$
4.3. A normal form for the resolvent equation

We consider again the resolvent equation (103)

\[(s^2I - P_0(D_1, i\omega_-)) \hat{u} = (s^2I - (A_1 D_1^2 - B(\omega_-))) \hat{u} = \hat{F}. \tag{113}\]

Introducing a new variable by

\[\hat{u} = A_1^{-1/2} \tilde{u}, \quad D_1 \tilde{u} = \sqrt{|s|^2 + |\omega_-|^2} \tilde{v}, \tag{114}\]

we obtain the slightly changed first order system

\[D_1 \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix} = \sqrt{|s|^2 + |\omega_-|^2} \tilde{M} \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix} + \frac{1}{\sqrt{|s|^2 + |\omega_-|^2}} \begin{pmatrix} 0 \\ -A_1^{-1/2} \hat{F} \end{pmatrix} \tag{115}\]

where

\[H(s', \omega') = A_1^{-1/2} \left( s'^2 I + B(\omega_-) \right) A^{-1/2}, \quad \tilde{M} = \begin{pmatrix} 0 & I \\ H & 0 \end{pmatrix}, \]

and \(s' = s/\sqrt{|s|^2 + |\omega_-|^2}\), \(\omega_- = \omega_- / \sqrt{|s|^2 + |\omega_-|^2}\) are scaled variables.

The associated eigenvalue problem is given by

\[\psi = \kappa' \varphi, \quad H(s', \omega') \varphi = \kappa' \psi, \tag{116}\]

i.e.,

\[\kappa'^2 \varphi = A^{-1/2} \left( s'^2 I + B(\omega_-) \right) A^{-1/2} \varphi. \tag{117}\]

(117) is a normalized form of (105).

Lemma 100 and (12) give us

Lemma 4.5. Let \(s' = i\xi' + \eta', \eta' \geq \eta' > 0\) for some positive constant \(\eta'_0\). Then there is a constant \(\delta > 0\) such that

\[|\text{Re} \kappa'| > \delta \quad \text{for all } s', \omega' \text{ with } \eta' \geq \eta'_0. \tag{118}\]

This gives us the normal form of \(M(s', \omega')\) for \(\eta' \geq \eta'_0 > 0\).

By Lemma 100, we obtain also

Lemma 4.6. For \(\eta' \geq \eta'_0 > 0\), there is a smooth transformation \(S = S(\omega', s')\) such that

\[S^{-1} \tilde{M} S = \begin{pmatrix} \tilde{M}^{11} & 0 \\ 0 & \tilde{M}^{12} \end{pmatrix}, \quad \tilde{M}^{11} + \tilde{M}^{12} \leq -\delta I, \quad \tilde{M}^{11} + \tilde{M}^{12} \geq \delta I. \tag{119}\]

We shall now derive a normal form of \(\tilde{M}\) for \(s'_0 = i\xi'_0\). We have

Lemma 4.7. Let \(s'_0 = i\xi'_0\) and let \(\omega'_0\) be fixed. \(H(\omega'_0, i\xi'_0)\) is symmetric and there is a unitary transformation \(U\) such that

\[U^* H U = \begin{pmatrix} H_{11} & 0 \\ 0 & H_{22} \end{pmatrix}, \tag{120}\]
where

\[
H_{11} = \begin{pmatrix}
\kappa_1^2 & 0 & \cdots & 0 \\
0 & \kappa_2^2 & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & \kappa_m^2
\end{pmatrix}, \quad \kappa_1^2 \geq \kappa_2^2 \geq \ldots \geq \kappa_m^2 > 0,
\]

(121)

\[
H_{22} = \begin{pmatrix}
\kappa_{m+1}^2 & 0 & \cdots & 0 \\
0 & \kappa_{m+2}^2 & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & \kappa_n^2
\end{pmatrix}, \quad 0 \geq \kappa_{m+1}^2 \geq \kappa_{m+2}^2 \geq \ldots \geq \kappa_n^2.
\]

(122)

where \(\kappa_j' = \pm \kappa_j' (\omega'_-, i\xi'_0)\) are the eigenvalues of (117). \(\kappa_{m+1}^2 = 0\) if and only if

\[\xi_0^2 = \beta_j |\omega_-'| \]

is an eigenvalue of \(B(\omega'_-)\), \(0 < \beta_{\min} \leq \beta_j \leq \beta_{\max}, j = 1, 2, \ldots, n\).

Also,

\[\text{if } \xi_0^2 < \beta_{\min} |\omega'_-|^2, \text{ then all } \kappa_j^2 > 0.\]

(123)

**Proof.** Since \(H(\omega'_-, i\xi'_0)\) is symmetric, we obtain (120)–(122).

If \(\xi_0^2 > \beta_{\max} |\omega'_-|^2\), then \(H\) is negative definite and all \(\kappa_j^2 < 0\). Correspondingly, if \(\xi_0^2 < \beta_{\min} |\omega'_-|^2\), then all \(\kappa_j^2 > 0\). If \(\kappa^2 = 0\), then (117) becomes

\[(B(\omega'_-) - \xi_0^2 I) \varphi = 0,
\]

i.e., \(\xi_0^2\) must be an eigenvalue of \(B(\omega'_-)\). Clearly, the reverse is also true. If \(\xi_0^2\) is an eigenvalue of \(B(\omega'_-)\), then there is a \(\kappa^2 = 0\). This proves the lemma.

To simplify the arguments we shall make a strong assumption which we shall relax at the end of the section.

**Assumption 4.8.** The eigenvalues \(\kappa_j^2\) are distinct.

In this case we can choose \(U = U(\omega'_-, \xi')\) as a smooth function of \(\omega'_-, \xi'\) in a neighborhood of \(\omega'_-, \xi'_0\). Also there is a constant \(d_0 > 0\) such that, in the whole neighborhood,

\[|\kappa_j - \kappa_i| \geq d_0 \text{ for all } i, j \text{ with } i \neq j.\]

(124)

Finally, we make the perturbation \(s' = i\xi' + \eta', -\eta_0 \leq \eta' \leq \eta_0, \eta_0 \ll 1\). We have

\[
U^*(\omega'_-, \xi')H(\omega'_-, s')U(\omega'_-, \xi') = U^*(\omega'_-, \xi')H(\omega'_-, i\xi')U(\omega'_-, \xi')
+ U^*(\omega'_-, \xi')A^{-1}U(\omega'_-, \xi')(2i\xi' \eta' + \eta^2).
\]

(125)

Since \(U^* A^{-1} U\) is strictly positive definite, its diagonal elements \(a_{jj} > 0\) are positive. This gives us

**Lemma 4.9.** For sufficiently small \(\eta_0\) which depends only on \(A^{-1}\) and (124), there exists a smooth nonsingular transformation \(S = I + \eta S(\omega'_-, s')\) such that

\[
\tilde{H}(\omega'_-, s') = S^{-1}U^* HUS = \begin{pmatrix}
H_{11} & 0 \\
0 & H_{22}
\end{pmatrix} + 2i\xi' \eta' \begin{pmatrix}
\tilde{a}_{11} & \cdots & 0 \\
\vdots & \ddots & \vdots \\
0 & \cdots & \tilde{a}_{nn}
\end{pmatrix},
\]

(126)

where \(\tilde{a}_{jj} = a_{jj} + O(\eta') > 0\) and \(H_{11}, H_{22}\) are given as before but with distinct eigenvalues.
Now we can construct the normal form for the resolvent equation (115). We introduce new variables by
\[ \tilde{u} = A_1^{-1/2}US \tilde{u}, \quad \tilde{v} = A_1^{-1/2}US \tilde{v} \]
and after a permutation we obtain

**Theorem 4.10.** In a neighborhood of \( \omega', \xi' \), the resolvent equation (113) can be transformed smoothly into

\[
D_1 \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix} = \sqrt{|s|^2 + |\omega'|^2} \begin{pmatrix} 0 & I \\ H(\omega', s') & 0 \end{pmatrix} \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix} + \frac{1}{\sqrt{|s|^2 + |\omega'|^2}} \begin{pmatrix} 0 \\ \tilde{F} \end{pmatrix}
\]

where \( \tilde{F} = -S^{-1}U^*A_1^{1/2}\tilde{F} \). By (126), the system (127) is composed of 2 \( \times \) 2 systems

\[
\begin{pmatrix} \tilde{u}_j \\ \tilde{v}_j \end{pmatrix}_x = \sqrt{|s|^2 + |\omega'|^2} \begin{pmatrix} 0 & 1 \\ \tilde{R}_j^2(\omega', s') & 0 \end{pmatrix} \begin{pmatrix} \tilde{u}_j \\ \tilde{v}_j \end{pmatrix} + \frac{1}{\sqrt{|s|^2 + |\omega'|^2}} \begin{pmatrix} 0 \\ \tilde{F}_j \end{pmatrix}
\]

where

\[ \tilde{R}_j^2(\omega, s) = \kappa_j^2(\omega'_-, i\xi') + 2i\tilde{a}_{jj}\xi'^2. \]

We shall now discuss the eigenvalues of the 2 \( \times \) 2 blocks

**Lemma 4.11.** Consider the eigenvalues of problem (117). Then

\[
|\kappa_j^2(\omega'_-, i\xi')| \geq \min_j \frac{|\beta_j| |\omega'_-|^2 - \xi'^2|}{|A_1|}, \quad |A_1| \text{ Euclidean norm of } A_1.
\]

**Proof.** Since \( H(\omega'_-, \xi') \) is symmetric, we have

\[
\left| \frac{1}{\kappa_j^2(\omega'_-, i\xi')} \right| \leq \left| A_1^{1/2} (B(\omega'_-) - \xi'^2I)^{-1} A_1^{1/2} \right|
\]

\[ \leq |A_1| \left| (B(\omega'_-) - \xi'^2I)^{-1} \right| = \frac{|A_1|}{\min_j |\beta_j| |\omega'_-|^2 - \xi'^2|}. \]

Therefore (129) follows. \( \square \)

We can express (129) also in another way. Let \( \xi'^2 = \beta |\omega'_-|^2 \). Then \( \xi'^2 + |\omega'_-|^2 = 1 \) implies

\[ |\omega'_-|^2 = \frac{1}{1 + \beta}, \quad \xi'^2 = \frac{\beta}{1 + \beta} \]

and (129) becomes

\[ |\kappa_j^2(\omega'_-, i\xi')| \geq \min_j |\beta_j - \beta| |A_1|(1 + \beta). \]

Thus, if \( \beta \) is not close to any \( \beta_j \), we can transform (128) smoothly to diagonal form and reduce the system to scalar equations with eigenvalues

\[ \kappa_j'(\omega'_-, s') = \pm \sqrt{\kappa_j^2(\omega'_-, \xi')} + 2i\xi'\eta'\tilde{a}_{jj}. \]

We shall now replace Assumption 4.8 by

**Assumption 4.12.** The eigenvalues of \( H_{22} \) are distinct.

We can prove
Theorem 4.13. Let \( s_0' = i\xi', \omega'_-, \) be fixed and assume that the eigenvalues \( \kappa_j^2 \) of \( H(\omega'_-, s_0') \) with \( \kappa_j^2 \leq 0 \), are distinct. Then there exists a neighborhood \( |s' - s_0'| + |\omega'_- - \omega'_0| \leq \sigma, \sigma > 0, \) in which we can transform

\[
\tilde{M} = \begin{pmatrix} 0 & I \\ H & 0 \end{pmatrix}
\]

smoothly into

\[
\begin{pmatrix}
\tilde{M}_{11} & 0 & 0 \\
0 & \tilde{M}_{22} & 0 \\
0 & 0 & \tilde{M}_{33}
\end{pmatrix}
\]

where \( \tilde{M}_{11}, \tilde{M}_{22} \) satisfy the inequalities of Lemma 4.6 and \( \tilde{M}_{33} \) is composed of \( 2 \times 2 \) blocks with \( \kappa_j^2 \leq 0 \). If \( \kappa_{m+1}^2(\omega'_0, i\xi'_0) < 0 \), then all the \( 2 \times 2 \) blocks of \( \tilde{M}_{22} \) can be transformed smoothly into

\[
\begin{pmatrix}
-k_j^r & 0 \\
0 & k_j^r
\end{pmatrix}, \quad \text{Re} \ k_j^r \geq \delta \eta_j' \text{ if } \eta_j' \geq 0, \quad k_j^r = k_j'(\omega'_-, s').
\]

If \( \kappa_{m+1}^2(\omega'_-, i\xi'_0) = 0 \), then the transformation

\[
S = \begin{pmatrix} 1 & \tilde{k}_{m+1}^r \\ -\kappa_{m+1}^r & 1 \end{pmatrix}, \quad \kappa_{m+1}^r = \kappa_{m+1}^r(\omega'_-, s'),
\]

transforms the corresponding block into upper triangular form in a neighborhood of \( \omega'_-, s'_0, \) i.e.,

\[
S^{-1} \begin{pmatrix} 0 & 1 \\ -\kappa_{m+1}^2 & 0 \end{pmatrix} S = \begin{pmatrix} -\kappa_{m+1}^r & d \\ 0 & \kappa_{m+1}^r \end{pmatrix}, \quad d = \frac{1 + |\kappa_{m+1}^r|^4}{1 + |\kappa_{m+1}^r|^2}.
\]

The transformation is continuous for \( \eta_j' > 0 \) and converges for \( \omega'_- \to \omega'_-, s' \to i\xi'_0, \) to \( S = I \) and \( \kappa_{m+1}^r(\omega'_-, i\xi'_0) \).

Proof. For \( s' = s'_0, \omega'_- = \omega'_-, \) we can transform \( \tilde{M} \) to the block diagonal form

\[
\begin{pmatrix} \tilde{M}_{11} & 0 \\ 0 & \tilde{M}_{22} \end{pmatrix}, \quad \tilde{M}_{jj} = \begin{pmatrix} 0 & I \\ H_{jj} & 0 \end{pmatrix}, \quad j = 1, 2.
\]

Since the eigenvalues of \( \tilde{M}_{11} \) are \( \pm \kappa_j, \ j = 1, 2, \ldots, m, \) we can split \( \tilde{M}_{11} \) into \( \tilde{M}_{11}^1, \tilde{M}_{11}^2 \) in a whole neighborhood.

Since the eigenvalues of \( \tilde{M}_{22} \) are distinct we obtain the blockform in the neighborhood. This proves the theorem. \( \Box \)

We can write the eigenvalue problem (27) also in another form

\[
(s^2 I - A_1 \kappa^2 + B(\omega'_-)) \hat{\varphi} = 0, \quad \hat{\varphi} = A^{-1/2} \varphi.
\]

Any \( \kappa^2 < 0 \) can be written as \( \kappa^2 = (i\omega_1)^2 = -\omega_1^2. \) Now (41) becomes

\[
(s^2 I + A_1 \omega_1^2 + B(\omega'_-)) \hat{\varphi} = \left(s^2 I + \hat{P}_0(\omega')\right) \hat{\varphi} = 0.
\]

Therefore the eigenvalues of \( \tilde{M}_{22} \) are eigenvalues of the symbol \( \hat{P}_0(\omega') \) (see (10)), and we can phrase Assumption 4.12 also as

Assumption 4.14. The eigenvalues of the symbol \( \hat{P}_0(\omega') \) are distinct.
By using Laplace and Fourier transformation we have shown that the system (1) behaves locally like a system of wave equations coupled by boundary conditions. Therefore we can proceed in the same way as in section 2
and section 3.1.

These results are also valid for general systems of symmetric hyperbolic systems with mixed terms.

We can also replace the last Assumption by

**Assumption 4.15.** The eigenvalues of $P_0(i\omega)$ have constant multiplicity. (For first order systems this is due to [5]).

**APPENDIX**

In this appendix we collect a number of auxiliary lemmas.

**Lemma A.1.** The solution of

$$y_x = \lambda y + F, \quad \text{Re} \lambda > 0, \quad 0 \leq x < \infty$$

satisfies the estimate

$$|y(0)|^2 \leq \frac{1}{2 \text{Re} \lambda} \|F\|^2, \quad \|y\|^2 \leq \frac{1}{(\text{Re} \lambda)^2} \|F\|^2, \quad \|F\|^2 = \int_0^{\infty} |F|^2 dx.$$  \hspace{1cm} (134)

**Proof.** Integration by parts gives us

$$(y, y_x) = -|y(0)|^2 - (y_x, y), \quad \text{i.e.,} \quad 2\text{Re}(y, y_x) = -|y(0)|^2.$$

Therefore

$$\frac{1}{2} |y(0)|^2 + \text{Re} \lambda \|y\|^2 = -\text{Re} \langle y, F \rangle \leq \|y\| \|F\|$$

$$\leq \frac{\alpha}{2} \text{Re} \lambda \|y\|^2 + \frac{1}{2\alpha \text{Re} \lambda} \|F\|^2, \quad \alpha > 0.$$  

With $\alpha = 2$ the first inequality follows. With $\alpha = 1$ the second inequality follows. \hspace{1cm} $\square$

**Lemma A.2.** The solution of

$$y_x = -\lambda y + F, \quad y(0) = g, \quad \text{Re} \lambda > 0, \quad 0 \leq x < \infty,$$

satisfies

$$\|y\|^2 \leq \frac{1}{\text{Re} \lambda} |g|^2 + \frac{1}{(\text{Re} \lambda)^2} \|F\|^2.$$  \hspace{1cm} (135)

**Proof.**

$$\langle y, y_x \rangle = 2 \text{Re} \langle y, y_x \rangle = -2(\text{Re} \lambda) |y|^2 + 2 \text{Re} \langle y, F \rangle.$$  

As $y \in L^2$, integrating we have

$$-|y(0)|^2 = -2\text{Re} \lambda \|y\|^2 + 2 \text{Re} \langle y, F \rangle$$

$$\leq -2\text{Re} \lambda \|y\|^2 + 2 \|y\| \|F\|$$

$$\leq -2\text{Re} \lambda \|y\|^2 + \text{Re} \lambda \|y\|^2 + \frac{\|F\|^2}{\text{Re} \lambda}.$$  

Thus,

$$\text{Re} \lambda \|y\|^2 \leq |y(0)|^2 + \frac{\|F\|^2}{\text{Re} \lambda}$$

and the lemma follows. \hspace{1cm} $\square$
Lemma A.3. Let \(a, b\) be real and consider \(\sqrt{a + ib}\) with \(-\pi < \arg(a + ib) \leq \pi\), \(\arg z = \frac{1}{2} \arg z\). Then, the following inequalities hold

\[
\begin{align*}
2^{-1/4} \sqrt{|a| + |b|} & \leq |\sqrt{a + ib}| \leq \sqrt{|a| + |b|} \\
2^{-3/4} |\sqrt{a + ib}| & \leq \sqrt{2^{-3/4} |a| + |b|} \leq |\sqrt{a + ib}| \leq \sqrt{|a| + |b|} \\
2^{-5/4} |\frac{b}{|\sqrt{a + ib}|}| & \leq 2^{-1} \frac{|b|}{|\sqrt{a + ib}|} \leq |\sqrt{a + ib}| \\
& \text{for } a \geq 0, \\
& \text{for } a \leq 0.
\end{align*}
\]

Proof. In polar notation \(a + ib = \rho e^{i\theta}\), \(\rho = \sqrt{a^2 + b^2} > 0\), \(-\pi < \theta \leq \pi\), and

\(\sqrt{a + ib} = \sqrt{\rho} e^{i\frac{\theta}{2}}\)

We have

\[
\sqrt{|a| + |b|} = \sqrt{\rho} \sqrt{\cos \theta + |\sin \theta|} \geq 2^{1/4} \sqrt{\rho}
\]

and the first inequality in (136) follows. The second inequality in (136) follows from the triangle inequality. If \(a \geq 0\) then \(\frac{\theta}{2} \in [-\pi/4, \pi/4]\) and (136) implies

\[
|\sqrt{a + ib}| \geq \Re \sqrt{a + ib} = \sqrt{\rho} \cos(\theta/2) \geq \frac{\sqrt{2}}{2} \rho \geq 2^{-3/4} \sqrt{|a| + |b|} \geq 2^{-3/4} |\sqrt{a + ib}|
\]

which is (137). To prove (138) notice that, as \(a \leq 0\),

\[
\frac{|b|}{\sqrt{|a| + |b|}} \leq \frac{|b|}{|\sqrt{a + ib}|} = \frac{\rho \sin \theta}{\sqrt{\rho}} = \sqrt{\rho} \frac{2}{2} \sin(\theta/2) \cos(\theta/2) \leq 2 \Re \sqrt{a + ib}
\]

therefore

\[
\frac{1}{2} \frac{|b|}{\sqrt{|a| + |b|}} \leq \Re \sqrt{a + ib} \leq |\sqrt{a + ib}|
\]

and the inequality follows from (136). \(\square\)

We shall now apply the last lemma to

\[\kappa = \sqrt{\omega^2 + \eta^2 - \xi^2 + 2i\xi\eta}, \quad \kappa = \sqrt{\omega^2 + \eta^2 - \xi^2}, \quad \kappa = \sqrt{\omega^2 + \eta^2}\]

In the following three lemmas we denote by \(\delta\) with \(0 < \delta < 1\) a fixed constant.

Lemma A.4. Let

\[
\delta_1 = 2^{-1/4} \sqrt{\delta}, \quad \delta_2 = 2^{1/2} (1 - \delta)^{1/4}, \quad \delta_3 = \min(\delta_1, \delta_2).
\]

Then

\[
|\kappa| \geq \begin{cases} 
\delta_1 \sqrt{\omega^2 + |s|^2} & \text{if } |\omega^2 + \eta^2 - \xi^2| \geq \delta (\omega^2 + |s|^2) \\
\delta_2 \sqrt{|s|^2 + \omega^2 \eta} & \text{otherwise}.
\end{cases}
\]

(139)

Also, always

\[
|\kappa| \geq \delta_3 \eta.
\]

(140)

Proof. By (136) we obtain, for the first case,

\[
|\kappa| \geq 2^{-1/4} \sqrt{|\omega^2 + \eta^2 - \xi^2| + 2|\xi|\eta} \geq 2^{-1/4} \sqrt{\delta} \sqrt{\omega^2 + |s|^2}.
\]

If \(|\omega^2 + \eta^2 - \xi^2| < \delta (\omega^2 + |s|^2)\), then

\[
2\xi^2 \geq (1 - \delta)(\omega^2 + \xi^2 + \eta^2) = (1 - \delta)(\omega^2 + |s|^2).
\]
Therefore
\[ |\kappa| \geq 2^{-1/4} \sqrt{2|\xi|\eta} \geq \sqrt{2\sqrt{1 - \delta \sqrt{\omega^2 + |s|^2 \eta}}}. \]

Also \( \sqrt{\omega^2 + |s|^2} \geq \eta \) implies (140). This proves the lemma. \( \square \)

**Lemma A.5.**

\[
\text{Re } \kappa \geq \begin{cases} 
2^{-5/4} |\kappa| & \text{if } \omega^2 + \eta^2 - \xi^2 \geq 0, \\
2^{-3/4} \sqrt{\omega^2 + |s|^2 \eta} & \text{if } \omega^2 + \eta^2 - \xi^2 < 0.
\end{cases}
\]

\[
\text{Re } \kappa \geq \delta_4 \eta, \quad \delta_4 = 2^{-3/4} \min(1, \delta_3).
\]

**Proof.** If \( \omega^2 + \eta^2 - \xi^2 \geq 0 \), then (137) gives us
\[
\text{Re } \kappa \geq 2^{-3/4} |\kappa| \geq 2^{-3/4} \delta_3 \eta.
\]

If \( \omega^2 + \eta^2 - \xi^2 < 0 \), then \( 2\xi^2 \geq \omega^2 + \eta^2 + \xi^2 = \omega^2 + |s|^2 \). Therefore (138) gives us
\[
\text{Re } \kappa \geq 2^{-5/4} \sqrt{\omega^2 + |s|^2 \eta} \geq 2^{-3/4} \eta.
\]

This proves the lemma. \( \square \)

**Lemma A.6.**

\[
|\kappa| \text{ Re } \kappa \geq \delta_6 \sqrt{\omega^2 + |s|^2 \eta}, \quad \delta_6 = \min \left( \delta_1 \delta_4, 2^{-5/4} \delta_2, 2^{-3/4} \right).
\]

**Proof.** If \( \omega^2 + \eta^2 - \xi^2 \geq 0 \), and \( |\omega^2 + \eta^2 - \xi^2| \geq \delta (\omega^2 + |s|^2) \), then (139) and (141) give us
\[
|\kappa| \text{ Re } \kappa \geq \delta_1 \sqrt{\omega^2 + |s|^2} \delta_4 \eta.
\]

If \( \omega^2 + \eta^2 - \xi^2 \geq 0 \), and \( |\omega^2 + \eta^2 - \xi^2| < \delta (\omega^2 + |s|^2) \), then (139) and (141) give us
\[
|\kappa| \text{ Re } \kappa \geq 2^{-5/4} |\kappa|^2 \geq 2^{-5/4} \delta_2 \sqrt{\omega^2 + |s|^2} \eta.
\]

Finally, if \( \omega^2 + \eta^2 - \xi^2 < 0 \), by (141) we obtain
\[
|\kappa| \text{ Re } \kappa \geq 2^{-3/4} \sqrt{\omega^2 + |s|^2} \eta.
\]

This proves the lemma. \( \square \)

**Lemma A.7.** Assume that, for the boundary condition 1), \( a > 0 \), \( |b| < 1 \). Then there is a constant \( \delta > 0 \) such that, for all \( \omega \) and \( s \) with \( \text{Re } s \geq 0 \),
\[
|s + a\kappa - ib\omega| \geq \delta \sqrt{|s|^2 + \omega^2}.
\]

For the proof, see Lemma 3 of [4].

Finally we have a lemma similar to Lemma A.4 and Lemma A.6 but for the normalized variables
\[
\kappa' = \sqrt{\eta^2 - \xi^2} + \omega'^2 + 2i\xi' \omega', \quad \xi'^2 + \omega'^2 = 1, \quad |\eta'| \ll 1.
\]
By Lemma A.3,

\[ |\kappa'| \geq 2^{-1/4} \sqrt{|-\xi'^2 + \omega'^2 + \eta'^2| + 2|\xi'| |\eta'|} \]

\[ \Re \kappa' \geq 2^{-3/4} \sqrt{|-\xi'^2 + \omega'^2 + \eta'^2| + 2|\xi'| |\eta'|} \quad \text{if } \xi'^2 \leq \omega'^2 + \eta'^2, \]

\[ \Re \kappa' \geq \frac{|\xi'| |\eta'|}{\sqrt{|-\xi'^2 + \omega'^2 + \eta'^2| + 2|\xi'| |\eta'|}} \quad \text{if } \xi'^2 > \omega'^2 + \eta'^2. \quad (141) \]

**Lemma A.8.** There is a constant \( \delta > 0 \) such that

\[ |\Re \kappa'| \geq \delta \eta', \quad |\kappa'| \geq 2^{-1/4} \eta', \quad |\kappa'| |\Re \kappa'| \geq \delta_6 \eta'. \]

where \( \delta_6 \) is that of Lemma A.6.

**Proof.** From Lemma A.6, dividing by \( \omega^2 + \xi^2 \),

\[ |\kappa'| |\Re \kappa'| = \frac{|\kappa| \Re \kappa}{\omega^2 + \xi^2} \geq \frac{\delta_6 \sqrt{\omega^2 + \xi^2}}{\omega^2 + \xi^2} \frac{\eta}{\sqrt{\omega^2 + \xi^2}} \geq \delta_6 \eta'. \]

Now if \( \omega'^2 - \xi'^2 \geq 0 \), then \( \omega'^2 - \xi'^2 + \eta'^2 \geq \eta'^2 \), and

\[ \sqrt{|\omega'^2 - \xi'^2 + \eta'^2| + 2|\xi'| |\eta'|} \geq \sqrt{\eta'^2 + 2|\xi'| |\eta'|} \geq \eta', \]

so that, by Lemma A.3,

\[ |\kappa'| \geq 2^{-1/4} \eta', \quad \text{and} \quad \Re \kappa' \geq 2^{-3/4} \eta'. \]

If \( \omega'^2 - \xi'^2 \leq 0 \) then \( |\xi'^2| \geq 1/2 \). From (141)

\[ |\kappa'| \geq 2^{-1/4} \sqrt{2} \eta' \geq 2^{1/2} \eta'. \]

This last estimate also holds for \( |\Re \kappa'| \) when \( \omega'^2 - \xi'^2 + \eta'^2 \geq 0 \). When \( \omega'^2 - \xi'^2 + \eta'^2 \leq 0 \) we just use \( |\omega'^2 - \xi'^2 + \eta'^2| + 2|\xi'| |\eta'| \leq \text{const} \). and from (141) the estimate for \( \Re \kappa' \) follows from (141). This proves the lemma.

We thank Prof. Oscar Reula who participated in the original discussions leading to this work.
